Abstract

Males of certain species belonging to the *Bactrocera dorsalis* complex are strongly attracted to, and readily feed on methyl eugenol (ME), a plant secondary compound that is found in over 480 plant species worldwide. Amongst those species is one of the world's most severe fruit pests the Oriental fruit fly, *B. dorsalis* s.s., and the former taxonomic species *B. invadens*, *B. papayae* and *B. philippinensis*. The latter species have been recently synonymised with *B. dorsalis* based on their very similar morphology, mating compatibility, molecular genetics and identical sex pheromones following consumption of ME. Previous studies have shown that male fruit fly responsiveness to lures is a unique phenomenon that is dose species-specific, besides showing a close correlation to sexual maturity attainment. This led us to use ME sensitivity as a behavioural parameter to test if *B. dorsalis* and the three former taxonomic species had similar sensitivity towards odours of ME. Using Probit analysis, we estimated the median dose of ME required to elicit species' positive response in 50% of each population tested (ED_{50}). ED_{50} values were compared between *B. dorsalis* and the former species. Our results showed no significant differences between *B. dorsalis* s.s., and the former *B. invadens*, *B. papayae* and *B. philippinensis* in their response to ME. We consider that the

Bactrocera males' sensitivity to ME may be a useful behavioural parameter for species delimitation and, in addition to other integrative taxonomic tools used, provides further supportive evidence that the four taxa belong to one and the same biological species, *B. dorsalis*.

Keywords

Bactrocera dorsalis, *B. invadens*, *B. papayae*, *B. philippinensis*, methyl eugenol, male response, lure sensitivity

Introduction

A number of fruit fly species in the *Bactrocera dorsalis* complex are pests of economic importance. The most notorious is the Oriental fruit fly, *B. dorsalis* (Hendel), a widely distributed and invasive species which includes the recently synonymised *B. invadens* Drew, Tsuruta & White, *B. papayae* Drew & Hancock and *B. philippinensis* Drew & Hancock. The presence of this species in the tropics and subtropics has caused significant damage by rendering infested fruits inedible and prohibiting fruit exports due to strict quarantine restrictions. Direct and indirect losses attributed to pestiferous tephritids are believed to be over US\$2 billion annually (Malavasi 2014). As a case in point, the 2014 ban on the entry of the popular mango (*Mangifera indica*) cv. 'Alphonso' from India to the EU countries (European Commission 2014) due to detection of Oriental fruit fly, made headlines globally and created an uproar in India, which is the largest mango producer in the world. Although the ban was lifted in January 2015 (European Commission 2015), the duration of the ban had adversely affected the lucrative mango export and livelihood of growers.

Further adding to the global fruit fly problem was the incursion into Africa of suspected Oriental fruit fly in 2003 (Lux et al. 2003), subsequently described as a new species, *B. invadens*, two years later (Drew et al. 2005). The *B. invadens*' African invasion was so serious that within three years of first incursion into Kenya, it had already been found to attack over 50 types of fruits in over 20 countries (Ekesi et al. 2006). Whilst *B. invadens*, *B. dorsalis*, *B. papayae* and *B. philippinensis* were known to appear similar morphologically and genetically, could interbreed and produce viable offspring as well as having identical male sex pheromone components (Tan et al. 2011, 2013, Schutze et al. 2013), it was only recently that all four species were synonymized as *B. dorsalis* (Schutze et al. 2015).

Previous studies have shown that male fruit fly responsiveness to the male lure methyl eugenol (ME) is a unique phenomenon that is dose species-specific, besides showing a close correlation to sexual maturity attainment (Wong et al. 1989, 1991, Wee and Tan 2000a). For example, *B. papayae* and *B. dorsalis* demonstrate similar ranges of sensitivity to ME at nanogramme levels, while *B. carambolae* has been shown to be at least 10 times less sensitive to ME compared to the former two species (Wee et al 2002). This led us to hypothesize that if *B. dorsalis*, *B. invadens*, *B. philippinensis* and *B. papayae* are different names for the one biological species, then their sensitivity to ME could be used as a behavioural parameter to confirm, or refute that assumption,

i.e. we evaluated if the sensitivity of those putative species to ME were significantly different (as might be expected if different biological species), or were the same (as might be expected if they are populations of the same biological species). In this paper, the minimum dose of ME needed to elicit species' positive response in 50% of the population tested (ED_{50}) was determined using Probit analysis and compared between the putative species as a species' delimiting tool.

Methods

Insects

Colonies of adult *B. dorsalis* and the former *B. invadens*, *B. philippinensis* and *B. papayae* were maintained in UPM insectary under strict quarantine. *Bactrocera papayae* were raised from locally collected infested starfruits, *Averrhoa carambola* L.; while *B. dorsalis*, *B. invadens*, *B. philippinensis* were obtained as pupae from the FAO/IAEA Insect Pest Control Laboratory in Seibersdorf, Austria in 2010. Pupae were imported into Malaysia using permits issued by the Director-General of Department of Agriculture Malaysia to AKW Hee. The origins of the Seibersdorf cultures are as follows: *B. dorsalis*, Saraburi, Thailand; *B. invadens*, Kenya; and *B. philippinensis*, Guimaras, the Philippines. All adult flies were provided with water and a mixture of sugar and hydrolysed protein (3:1 w/w) *ad libitum*. The flies were bred under conditions of 25–29 °C with 83–90% relative humidity, and a 12 L: 12 D photoperiod. Male flies were separated within three days of emergence (DAE) to prevent mating and were maintained in separate cages (30 cm × 30 cm × 30 cm) until required for bioassay at 19 DAE.

Chemical preparation

Different concentrations of ME (50, 100, 300, 500, 700 and 1000 ng per 5 µl of absolute ethanol, respectively) were prepared by serial dilution from pure ME (>99.8% purity; Merck-Schuchardt, Germany) following preliminary dose-response tests that showed attraction of male flies to ME of between 15–85%, which is in the linear portion of the population response curve (Heong et al. 2013). The use of six dilutions exceeds the minimum of five suggested for studies of this type by Robertson et al. (2007).

Probit regression of male flies' attraction to methyl eugenol

Laboratory bioassays with sexually mature and virgin male flies for their attraction to ME were conducted with slight modifications from the protocol of Wee et al. (2002). Males (30 males per replicate per cage [40 cm × 40 cm × 40 cm]) were acclimatized for 24 h before experimentation, in an isolated indoor area to prevent exposure of ME to

other colonies of flies that were yet to be assayed for ME response. Starting with 50 ng, the lowest concentration, 5 μ l of diluted ME was dispensed using a Hamilton® 5 μ l syringe onto a filter paper disc (3 cm \times 3cm; Whatman® No.1) placed in a disposable Petri dish. During the bioassay, we promptly removed any male that approached the ME spot and attempted to feed. After 5 min, the total number of flies that responded positively was recorded. The same procedure was conducted for new batches of males at higher ME concentrations. There were between 5–9 replicates performed for each dosage and putative species using flies from different cohorts on different days. Absolute ethanol (>99%) was used as a control. All used filter papers and petri dishes were securely disposed in airtight containers to remove traces of ME from the laboratory environment.

The data obtained were pooled and subjected to Probit analyses using the PoloPlus software (LeOra Software 2002) based on Finney (1971). Probit regressions along with ED₅₀ (effective median dose – that dose which elicits a response in 50% of the population tested) values were generated. Regression lines fitted to the dose response curves were subjected to a parallelism test using PoloPlus. This is necessary as relative potency, a measure of the species' responses to ME (based on ratios of ED₅₀), can only be valid when those ME dose-response regression lines are found to be parallel (Robertson et al. 2007; Heong et al. 2013).

Results

The male flies displayed typical behaviour in response to ME i.e. immediate zig-zag flying in locating the source of ME upon sensing the lure, followed by compulsive feeding on ME. When offered to the flies, ME attracted all four putative species at all of the tested doses (Figure 1). Approximately 25% of *B. dorsalis* responded to 50 ng of ME, which was the lowest concentration of ME tested and their responses were observed to gradually increase when subjected to higher dosages (Figure 1). The ED₅₀ response to ME for *B. dorsalis* males was 268 ng (Table 1). Similar behavioural responses were also observed in the males of the other three putative species. At the lowest dose of 50 ng, ME attracted 18%, 22% and 16% of *B. invadens*, *B. philippinensis* and *B. papayae* males, respectively (Figure 1), with their corresponding ED₅₀ values being 222 ng, 256 ng and 247 ng (Table 1). The validity of the ED₅₀ values was confirmed with heterogeneity factors of each species' response to ME showing values < 1 (*B. dorsalis*, 0.484; *B. invadens*, 0.714; *B. philippinensis*, 0.502 and *B. papayae*, 0.859), indicating the data fits well with the model of standardized residuals when plotted against the predicted values. The likelihood ratio test of parallelism revealed that the slopes of the regression lines for *B. dorsalis*, *B. invadens*, *B. philippinensis* and *B. papayae* were not significantly different (Figure 2) ($p > 0.05$; $\lambda^2 = 7.27$; $df = 3$). This allowed us to compare the relative potencies of the four species to ME. The attraction of *B. dorsalis*, *B. invadens*, *B. philippinensis* and *B. papayae* males to ME were found to be not significantly different based on their relative potency values which ranged between 0.9 and 1.1 (Table 1). In all controls, no males were attracted to filter paper containing absolute ethanol.

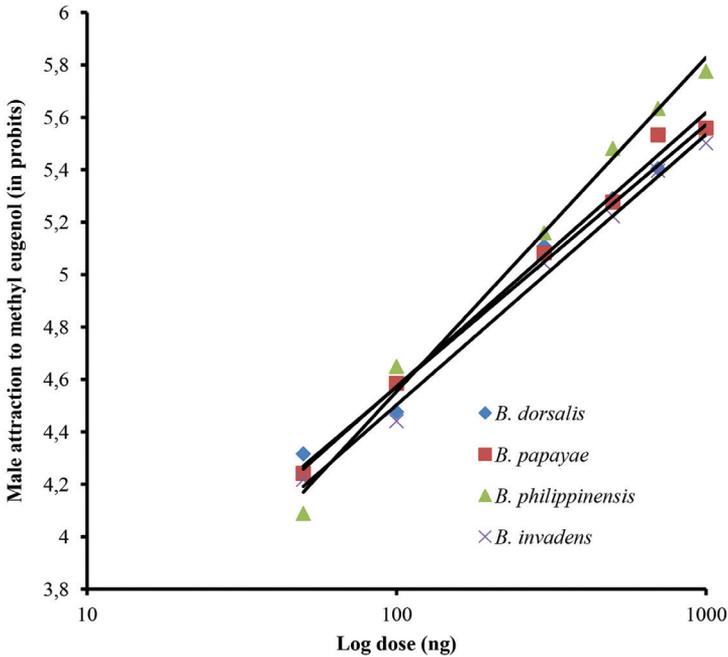

Figure 2. Probit lines of *B. dorsalis* and the former taxa *B. papayae*, *B. philippinensis* and *B. invadens* attraction to methyl eugenol.

Table 1. Probit analysis of male attractancy to methyl eugenol for *Bactrocera dorsalis* and the former taxa *B. papayae*, *B. philippinensis* and *B. invadens*.

Species	n ^a	Regression equation	χ^2	df	ED ₅₀ ^b (ng)	95% fiducial limits (ng)		Relative potency
						Lower	Upper	
<i>B. papayae</i>	210	y=1.108x-2.651	3.435	4	247	211	287	1.0
<i>B. philippinensis</i>	330	y=1.043x-2.511	2.008	4	256	224	290	1.0
<i>B. invadens</i>	270	y=1.266x-2.970	2.857	4	222	195	250	0.9
<i>B. dorsalis</i>	210	y=1.002x-2.433	1.936	4	268	226	316	1.1

^a n - number of insects tested per dose

^b ED₅₀ (effective median dose) is the dose required to elicit a positive response in 50% of the fruit fly population tested.

Discussion

Bactrocera dorsalis and the three former species *B. invadens*, *B. philippinensis* and *B. papayae* all showed similar sensitivity to the male lure, ME, with non-significant differences in ED₅₀ and potency values. Only marginal difference in the ED₅₀ between *B. papayae* and *B. dorsalis* in the current study is in contrast to our earlier work that showed approximately twice the level of ED₅₀ of *B. papayae* over *B. dorsalis* (Wee et al. 2002). We believe that the discrepancy in those ratios is attributed to the different geographical strains of *B. dorsalis* used, as the strain that was used by Wee et al. originated from Taichung, Taiwan, whilst the current strain used in this study originated from Saraburi, Thailand. Further, it must be noted that there was also no significant difference in the consumption of ME between *B. dorsalis* and *B. papayae* (Wee et al. 2002). The absence of parallelism test in Wee et al. was due to the fact that the inclusion of *B. carambolae* in that study elicited a very high ED₅₀ value (17 and 9 times higher than that of *B. dorsalis* and *B. papayae*) that resulted in the unsuitability of parallelism test of the regression lines for that study.

ME is found naturally in over 480 plant species (Tan and Nishida 2012) and is a pheromone precursor/booster for ME-sensitive *Bactrocera* species (Tan and Nishida 1996, Tan et al. 2014). Synthetic ME is widely used to control pestiferous *Bactrocera* species such as *B. dorsalis* in male annihilation programmes (Steiner et al. 1965, Vargas et al. 2014). However, it was not until the discovery that the responses of male fruit fly species such as *B. dorsalis* and *B. carambolae* to ME was quantifiable (Wee et al 2002), that we have used male ME response as a species' delimitation tool. As an example, the fact that *B. carambolae* is able to interbreed with *B. papayae* and produce viable offspring both in the laboratory and in the wild (Wee and Tan 2000b, 2005, Tan 2003; but see Schutze et al. 2013) suggested that the former might be a sub-species belonging to a single species. However, that male *B. carambolae* possess significantly lower sensitivity to ME compared with that of *B. dorsalis* in cage assays (Wee et al. 2002) further prompted efforts to evaluate the status of *B. carambolae* leading to the recognition that

B. carambolae is currently a distinct, perhaps an incipient, species from that of *B. dorsalis* (Schutze et al. 2015).

An important applied finding of this study, separate to the species delimitation issue, involves the use of ME in the field as a pest control. When ME is applied in the field, the different levels of male attraction to ME between species may impact on chances of male annihilation success. In the case of *B. dorsalis* and the former taxonomic species *B. invadens*, *B. papayae* and *B. philippinensis*, application of male annihilation technique against those flies is not expected to affect the success of the programme given that all four species (now synonymised as *B. dorsalis*) have been proven to have similar sensitivities to ME.

Acknowledgements

The approval granted by the Director-General of Agriculture Malaysia to Alvin K.W. Hee to bring in live pupae shipments of *B. dorsalis*, *B. philippinensis* and *B. invadens* from IPCL, Seibersdorf is much appreciated. The financial support from FAO/IAEA offered to Keng-Hong Tan through IAEA research contract no. 16160 is also gratefully acknowledged. We also thank Todd E. Shelly for his critical comments on an earlier draft of the manuscript.
