## Abstract

*Niveas* Rota, new genus, and its two new species, *N. agassizi* Rota, new species, and *N. kone* Rota, new species, are described and illustrated. *Niveas* is assigned to the subfamily Choreutinae based on morphological and molecular data. *Niveas agassizi* is currently known only from Kenya and only from female specimens. *Niveas kone* has been found on the Solomon Islands and in Papua New Guinea (PNG). In PNG, larvae of this species have been reared from several species of *Ficus* (Moraceae). The two species are superficially quite dissimilar from each other. However, they share features in wing pattern and venation, as well as female genitalia, and the molecular data strongly support the monophyly of *Niveas*.

## Keywords

Alpha taxonomy, DNA barcoding, *Ficus* spp., Kenya, *Niveas agassizi*, *Niveas kone*, Papua New Guinea, Solomon Islands, phylogenetics

## Introduction

Choreutidae, commonly known as metalmark moths, are a family of micro-moths with a worldwide distribution. The family is most species-rich in the tropics, and, as is the case for numerous other small tropical invertebrates, much of its richness is still unknown to science (unpublished data). Currently, 406 species of choreutids are described (Nieukerken et al. 2011).

Choreutids are medium-sized micro-moths with wingspans ranging from about one to two centimeters, often with bright colors and iridescent markings on their wings (Diakonoff 1986). They are diurnal with only some species attracted to lights at night (personal observation), making them a fairly rare group in museum collections. In our experience, large-scale rearing projects result in finding more species of choreutids than employing light traps.

Through exactly such efforts over the past 20 years in Papua New Guinea (PNG), the Binatang Research Center (BRC), with a large international group of collaborators focusing on the ecology of herbivorous insects and their host plants (Miller et al. 2003; Craft et al. 2010; Novotny et al. 2010; Hrcek et al. 2011; Hrcek et al. 2013; Miller et al. 2013), the number of known species of choreutids and our knowledge of their biology have greatly increased. One of the many new species of choreutids found in PNG during this project is sufficiently different from all described species that it requires a new genus.

Coincidentally, through separate collecting efforts by David Agassiz in Africa, a related species was discovered in Kenya. Herein these two species, as well as the genus to which they belong, are described and illustrated, and the phylogenetic position of the new genus within the family is discussed.

The shared presence of the terminal black band with white spots in the forewing (arrows in Figs 1, 3) was the first indication that *N. kone* Rota, sp. n. and *N. agassizi* Rota, sp. n. might be related. Initially this relationship seemed unlikely because of the disjunct geographical distribution of the two (*N. kone* being distributed in the Australasian Region and *N. agassizi* in the Afrotropical Region) and because their DNA barcodes did not suggest a close relationship. However, once the similarities in wing venation and female genitalia were noticed, and we included nuclear genes in the analysis with a more extensive choreutid molecular dataset, the results strongly supported the close relationship between *N. kone* and *N. agassizi*.

## Methods

All material examined is listed in Table 1. Layered photographs of specimens and slides were taken using an Olympus SZX16 microscope with motorized focus drive attached to an Olympus E520 digital camera. The photographs were then combined by using the programs Deep Focus 3.1 and Quick Photo Camera 2.3. The wing venation drawing was made digitally in Adobe Illustrator CS3 overlaid on top of a slide photograph.

**Table I.** Material examined.

All images were improved in Adobe Photoshop CS3. Genitalic dissections and terminology follow Rota (2008b).

Field sampling and rearing protocols for the PNG material are detailed in Miller et al. (2003; 2013), Craft et al. (2010), and Novotny et al. (2010). The Plant List website (2010) was used for host plant names. Latitude, longitude, and altitude data for the collecting localities is in Table 2.

The molecular phylogeny dataset included three outgroups and 40 species of ingroup taxa, including two individuals each of *Niveas kone* and *N. agassizi* totaling 45 terminal units. We analyzed data from eight genes: COI (mitochondrial), CAD, EF1 $\alpha$ , GAPDH, IDH, MDH, RpS5, and wingless (all nuclear) (Wahlberg and Wheat 2008). The final alignment was 6187 base pairs long. Molecular sequences for all taxa except *N. kone* and *N. agassizi* are from Rota (2011) and Rota and Wahlberg (2012), and their GenBank accession numbers can be found there. For the specimens of *N. kone* (660733) and *N. agassizi* (Ch\_JR44\_1), DNA extraction was done from whole abdomens, which were later used for dissection of genitalia. Because the DNA amplification methods described by Wahlberg and Wheat (2008) did not work for obtaining sequences of nuclear genes from these specimens, suggesting that their DNA was too degraded for the standard approach, we used newly-designed primers (Niklas Wahlberg, unpublished) (Table 3) to amplify short fragments of the nuclear genes (see Table 4 for total number of base pairs for each gene fragment amplified and the GenBank accession numbers for fragments longer than 200 base pairs). For sequence storage and manipulation we used the VoSeq application (Peña and Malm 2012). The nexus file with the alignment is available from the Figshare Digital Repository: doi: 10.6084/m9.figshare.811841

Both maximum likelihood (ML) and Bayesian phylogenetic analyses were performed. ML analysis of unpartitioned data was conducted using RAxML blackbox available online (Stamatakis et al. 2008) with the GTR+G model and 100 bootstraps. Bayesian analysis of data partitioned using the program TIGER (Cummins and McInerney 2011) as described in Rota and Wahlberg (2012) was carried out in MrBayes v. 3.2 (Ronquist et al. 2012) for 10 million generations with one cold and three heated chains, sampling trees every 1000 generations. The analyses were run on the freely available Bioportal server (University of Oslo, Norway). The convergence was assessed

Guelph, using their standard methodology (Craft et al. 2010; Hrcek et al. 2011; Wilson 2012). They are deposited in GenBank as accessions listed in Table 1, and their full data including images are in the Barcode of Life Database (<http://www.boldsystems.org>; see Ratnasingham and Hebert 2007; 2013). These sequences were also analyzed with MrBayes v. 3.2 (unpartitioned dataset, 2 million generations).

## Results

### Taxonomy

#### *Niveas* Rota, gen. n.

<http://zoobank.org/F352952E-0F21-464F-BD1E-278C9A0679C1>

<http://species-id.net/wiki/Niveas>

Figs 1–9

**Type species.** *Niveas kone*.

**Material examined.** See Table 1.

**Distribution.** Kenya, Papua New Guinea, Solomon Islands.

**Diagnosis.** *Niveas* can be easily distinguished from most genera of choreutids by the wing pattern (Figs 1, 3). Superficially, species of *Niveas* are similar to some species of *Anthophila* and *Choreutis*, but there is no known species in either of the latter two genera with a black terminal band enclosing white spots in the forewing as in *N. agassizi* and *N. kone*. (Figs 1, 3). Forewing venation with only four radial branches or with  $R_4$  and  $R_5$  fused in the basal half is also diagnostic for the genus. Female genitalia with paired concave sclerotizations on A7 sternite are also unique to *Niveas*.

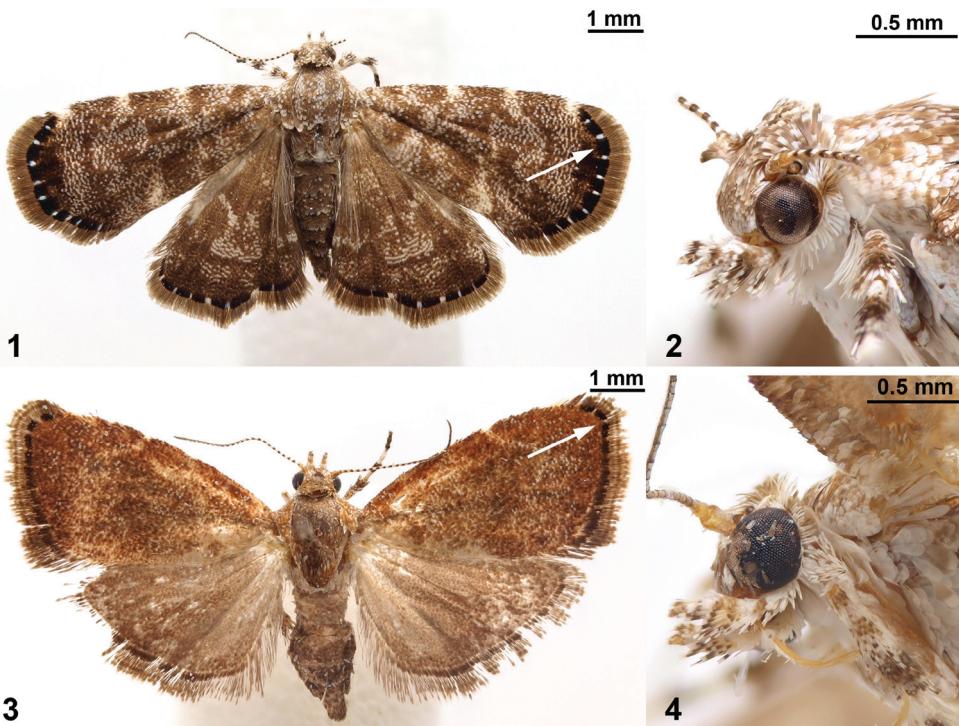

**Description.** *Head.* Labial palpi with projecting ventral scale tufts (Figs 2, 4).

*Wings.* Forewing veins R four-branched in *N. kone* (Fig. 5), five-branched in *N. agassizi* (Fig. 6), with  $R_4$  and  $R_5$  fused in basal 3/5; CuP present at termen for 1/3 to 1/5 wing length, extending as fold further towards base. Hindwing ten-veined, with  $M_2$  in close proximity to the basally fused  $M_3$  and CuA<sub>1</sub> (*N. agassizi*) or nine-veined, apparently with  $M_3$  and CuA<sub>1</sub> completely fused into a single vein (Figs 5, 6).

*Male genitalia.* Tegumen rounded on top, tuba analis extending beyond tegumen; vinculum as inverted trapezoid ventrally emarginate; valva with costal margin straight, ventral margin rounded, ending with a horn-like projection; phallus twice as long as valva (Fig. 7).

*Female genitalia.* Apophyses anteriores slightly longer than posteriores; ostium bursae on A7 with a more or less strongly sclerotized antrum; ductus bursae straight, not coiled, with strong lateral sclerotizations; corpus bursae as a single sac (*N. agassizi*) or divided into two sacs (*N. kone*) with one or more signa. A7 sternite with paired, somewhat rounded, concave sclerotizations proximally, clearly visible in *N. kone* (Fig. 8), and slightly less so in *N. agassizi* (Fig. 9).

**Host plants.** Genus *Ficus* (Moraceae).

**Figures 1–4.** *Niveas kone*: 1 Habitus 2 Head. *Niveas agassizi*: 3 Habitus 4 Head. (In Figs 1 and 3 arrows point at the terminal black band enclosing white spots.)

**Etymology.** The generic name is derived from Latin *niveum*, meaning snowy, in reference to speckles of white-tipped scales in the wings of the type species; it is not treated as a Latin word and is feminine in gender.

***Niveas kone* Rota, sp. n.**

<http://zoobank.org/9EA367B0-6B92-48FA-8075-D8D0D0BFA566>

[http://species-id.net/wiki/Niveas\\_kone](http://species-id.net/wiki/Niveas_kone)

Figs 1, 2, 5, 7, 8

**Material examined.** See Table 1.

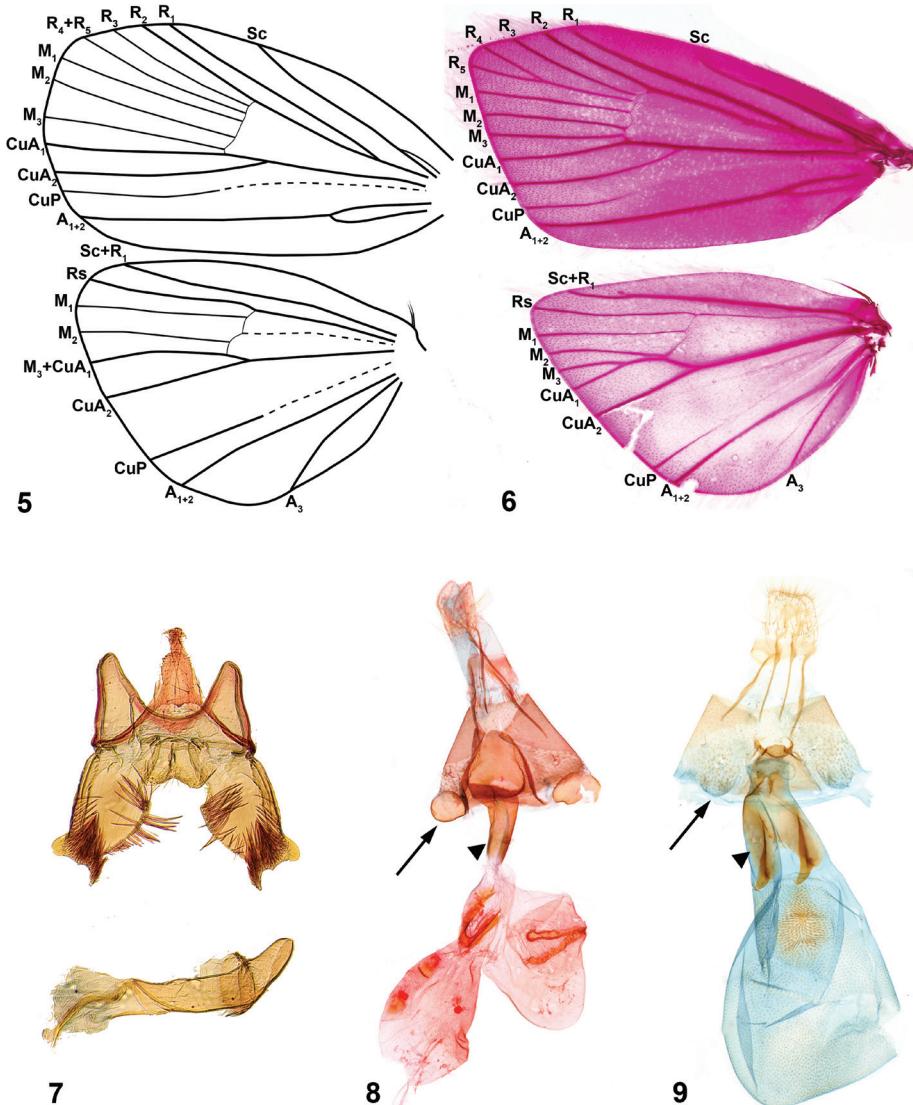

**Material deposited.** The holotype and most paratypes will be retained at USNM, with paratypes distributed to PNG National Agriculture Research Institute (Port Moresby), BMNH, Bishop Museum, Naturalis (Leiden), and CSIRO (Canberra).

**Distribution.** Papua New Guinea, Solomon Islands.

**Diagnosis.** *N. kone* can be separated from all other known choreutids based on its wing pattern (Fig. 1). Superficially, it is similar to a few species of *Brenthia* Clemens, 1860 and *Litobrenthia* Diakonoff, 1978 owing to its background color, but it lacks iridescent

spots along forewing termen, which are always present in those two genera. Both male and female genitalia are very distinct from those of other choreutids (Figs 7, 8).

**Description.** *Head.* Fig. 2. *Wings.* Fore- and hindwing with brown background color, speckled with white-tipped scales in an irregular pattern; a distinct black band along termen of both wings within which are more or less equidistant white spots (Fig. 1). *Male genitalia.* As for the genus (Fig. 7). *Female genitalia.* Corpus bursae split

**Figures 5–9.** *Niveas kone:* 5 Wing venation 7 Male genitalia 8 Female genitalia. *Niveas agassizi:* 6 Wing venation 9 Female genitalia. (In Figs 8 and 9 arrows point at the A7 sternite sclerotizations, and triangles point at the lateral sclerotizations on the ductus bursae.)

into two sacs; one sac with a V-shaped signum, the other with two round signa (Fig. 8). *Immature stages.* Fig. 12. See a brief note in text.

**Host plants.** *Ficus botryocarpa* Miq., *F. nodosa* Teijsm. & Binn., *F. phaeosyce* K. Schum. & Lauterb., *F. pungens* Reinw. ex Blume, *F. variegata* Blume, and *F. wassa* Roxb. (Moraceae).

**Etymology.** The species is named after the Finnish Kone Foundation (Koneen Säätiö) in appreciation of their funding of this work. The name is a noun in apposition.

### *Niveas agassizi* Rota, sp. n.

<http://zoobank.org/7F08322B-C0D2-450C-9DFF-ED9E4FEA5892>

[http://species-id.net/wiki/Niveas\\_agassizi](http://species-id.net/wiki/Niveas_agassizi)

Figs 3, 4, 6, 9

**Material examined.** See Table 1.

**Material deposited.** The holotype will be deposited in National Museums of Kenya (Nairobi) (NMK), with paratypes to USNM, BMNH and NMK.

**Distribution.** Kenya.

**Diagnosis.** *N. agassizi* can be separated from other known choreutids by the wing pattern (Fig. 3). It is superficially similar to some species of *Choreutis*, but the latter usually have forewings with apparent patterning, and this is absent in *N. agassizi*. Female genitalia are very distinct from those of other choreutids (Fig. 9).

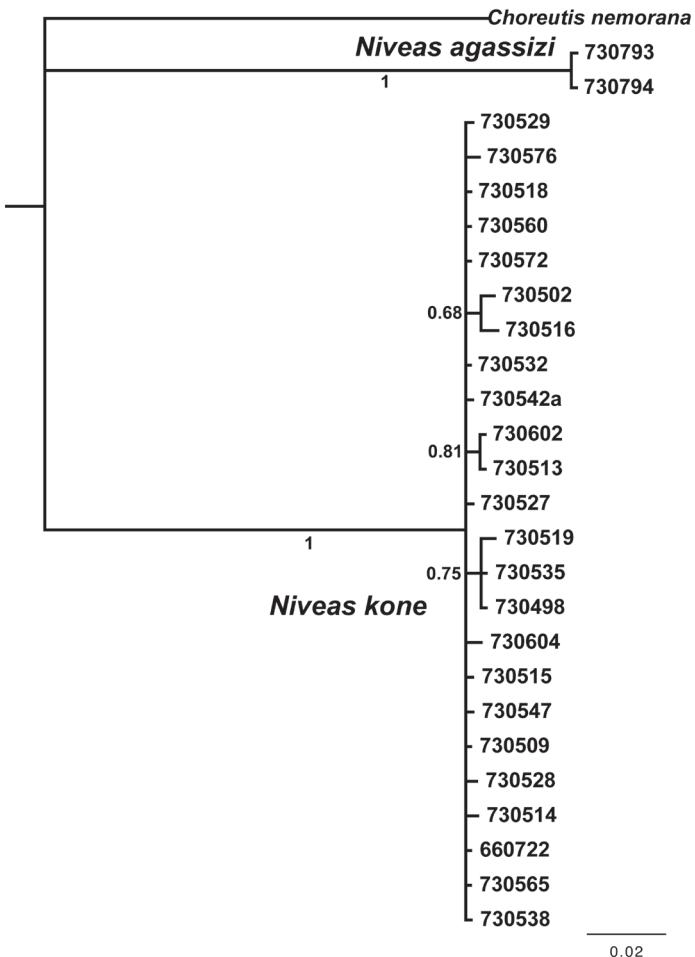

**Description.** Male unknown. *Head.* Fig. 4. *Wings.* Forewing bronze-brown with speckled white-tipped scales over most of its surface; distinct dark brown to black band along termen with two small white spots at apex; hindwing light brown (Fig. 3). *Male genitalia.* Unknown. *Female genitalia.* Ductus bursae short and wide, opening into large corpus bursae, with one oval signum (Fig. 9). *Immature stages.* Unknown.

**Host plants.** Unknown.

**Etymology.** This species is named after David Agassiz, who collected all the known specimens and made many significant contributions to our knowledge of African micro-moths. The name is a noun in the genitive case.

### Remarks

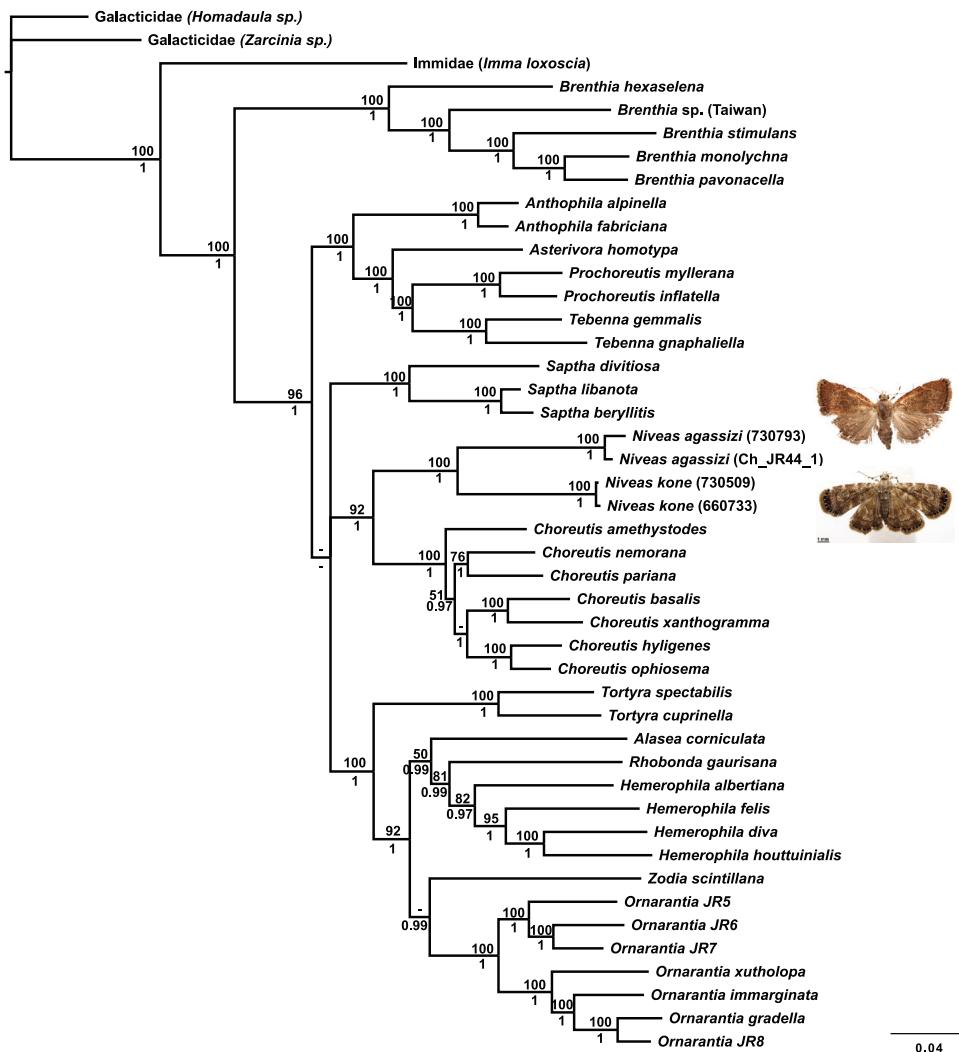

We obtained 19 full-length barcodes of *Niveas kone*, as well as 5 shorter fragments. These form cluster AAB7478 in the Barcode of Life Database (accessed 29 August 2013), and using the RESL algorithm as implemented there (Ratnasingham and Hebert 2013), the maximum distance between the COI sequences for members of the species is 0.65%, whereas the distance to the nearest cluster (*N. agassizi*) is 9.22%. In a Bayesian analysis of the COI sequences, all *N. kone* and all *N. agassizi* specimens grouped together with the other members of their species with very high branch support (PP=1) (Fig. 10).

**Figure 10.** DNA barcode tree from a Bayesian analysis showing low divergence within species and high between species of *Niveas*. Numbers below or next to branches are Bayesian posterior probabilities. Specimen ID numbers are used as labels for the terminal branches.

The placement of *Niveas* in the choreutid generic phylogeny is very strongly supported. *Niveas* clearly belongs within the subfamily Choreutinae (PP=1; ML BS=96), and it appears to be the sister group of *Choreutis* (PP=1.00; ML BS=92) (Fig. 11).

Further comments on the biology of *Niveas kone*: Over the years, BRC field teams have encountered larvae identified as *Niveas kone* (as project morphospecies TORT015) 118 times, of which 62 were reared to adults, usually on *Ficus nodosa* and *Ficus variegata*, but also on four other species of *Ficus* (see full host plant list under *N. kone* description). Larvae have been found in all months except April and November, and are described by BRC staff as being green-clear-whitish in color, with short white hairs, and one spot on the side of the head (Fig. 12). Larvae of *N. kone* share the presence of short hairs with other Choreutinae (Rota 2005), which is unlike Brenthiinae

**Figure 11.** Phylogenetic tree from a Bayesian analysis showing the position of *Niveas* in relation to other choreutid genera. Maximum likelihood (ML) bootstraps are shown above branches, and Bayesian posterior probabilities (PP) are below branches; dashes represent ML bootstraps < 50 and PP < 0.95.

larvae, which possess very long hairs (Rota 2008a). Project field notes indicate that the shelters are distinct from other local Choreutidae in having strong white webbing. BRC has encountered them most commonly in the lowland coastal areas around Madang (city), but also in the coastal mountains behind Madang (up to about 100 m elevation), and at Wanang in the Ramu River Basin (115 m). The species has been recorded in publications (e.g., supplement to Novotny et al. 2010) and online databases as TORT015, misidentified as *Brenthia* sp. Based on locality information provided by Taylor and Maffi (1978: 185, 212), the Solomon Islands specimens are from lowland and foothill localities near Honiara, Guadalcanal; they were collected in light traps.

**Figure 12.** A photograph of the *Niveas kone* larvae made in the field.

Taxon descriptions are also organized in tabular format for ease of comparison (see Appendix).

## Discussion

The two species of *Niveas* described herein are superficially quite different, but upon closer examination it becomes apparent that they share a number of morphological features. We consider the following as potential autapomorphies of *Niveas*: fusion or reduction in R veins in the forewing (Figs 5, 6); presence of round, concave sclerotizations on the A7 sternite in females (arrows in Figs 8, 9); strong lateral sclerotizations at the base of the ductus bursae (triangles in Figs 8, 9); and the presence of a terminal black band with white spots in the forewing (arrows in Figs 1, 3). In all other Choreutinae genera there are five fully-separated radial veins in the forewing; the A7 sternite in the female, as well as the base of the ductus bursae, are evenly sclerotized; and if present, a black terminal band in the forewing lacks white spots.

The split between *N. kone* and *N. agassizi* has presumably happened a long time ago based on the large COI divergence between them and the length of branches in the phylogenetic analysis including the nuclear genes. We considered assigning each species to its own monotypic genus because of their different external appearance, as well as some of the differences in venation and some aspects of female genitalia. It is unfortunate that *N. agassizi* is known from females only as perhaps the morphology of the male genitalia would help clarify the status of this species. However, we believe that *N. kone* and *N. agassizi* being each other's closest relatives among the currently known species of choreutids is best conveyed by assigning them to a single genus and therefore we opted for this more conservative approach. It is conceivable that other species of *Niveas* that might bridge this gap in both genetic and morphological variation will be discovered in the future. On the other hand, it is also possible that a new genus will need to be erected to accommodate *N. agassizi* and its currently unknown relatives.

## Acknowledgements

Papua New Guinea: This paper stems from a rearing campaign led by Vojtech Novotny, George Weiblen, Yves Basset, and Scott Miller, and supported by the US National Science Foundation (grants DEB-0211591, 0515678 and others), Czech Science Foundation grant 206/09/0115 and others, and Czech Ministry of Education & European Union grant CZ.1.-07/2.3.00/20.0064. We thank the staff at the PNG Binatang Research Center for field assistance, PNG land owners for access to field sites and assistance, and PNG agencies for permits. DNA barcoding was provided by Paul Hebert through a grant from Genome Canada and the Ontario Genomics Institute in support of the iBOL project. Karolyn Darrow, Lauren Helgen and Margaret Rosati provided assistance at the Smithsonian. Kenya: We thank David Agassiz for sharing his material of African choreutids and the National Museums of Kenya for facilitating our collaboration. Phylogenetics: We thank Niklas Wahlberg for designing primers used in this project; and Carlos Peña and Eero Vesterinen for laboratory assistance. Phylogenetic analyses were conducted on the freely available Bioportal cluster (<http://www.bioportal.uio.no>) and RAxML blackbox (<http://phylobench.vital-it.ch/raxml-bb/>). We thank John Brown and an anonymous reviewer for helpful comments on an earlier version of the manuscript. SEM also thanks the Natural History Museum, London, Bishop Museum, Honolulu, and International Center for Insect Physiology and Ecology, Nairobi, for their continued support of this research program. JR was funded by the Finnish Kone Foundation experienced researcher grant during this project.

## Appendix

Taxon descriptions organized in tabular format for ease of comparison.

Taxon	<i>Niveas</i> Rota, gen. n.	<i>Niveas</i> <i>kone</i> Rota, sp. n.	<i>Niveas agassizi</i> Rota, sp. n.
Type species	<i>Niveas zone</i>		
Material examined	See Table 1.	See Table 1.	See Table 1.
Material deposited		The holotype and most paratypes will be retained at USNM, with paratypes distributed to PNG National Agriculture Research Institute (Port Moresby), BMNH, Bishop Museum, Naturals (Leiden), and CSIRO (Canberra).	The holotype will be deposited in National Museums of Kenya (Nairobi) (NMK), with paratypes to USNM, BMNH and NMK.
Distribution	Kenya, Papua New Guinea, Solomon Islands.	Papua New Guinea, Solomon Islands.	Kenya.
Diagnosis	<i>Niveas</i> can be easily distinguished from most genera of choreutids by the wing pattern (Figs 1, 3). Superficially, species of <i>Niveas</i> are similar to some species of <i>Anthophila</i> and <i>Choreutis</i> , but there is no known species in either of the latter two genera with a black terminal band enclosing white spots in the forewing as in <i>N. agassizi</i> and <i>N. kone</i> . (Figs 1, 3). Forewing venation with only four radial branches or with $R_4$ and $R_5$ fused in the basal half is also diagnostic for the genus. Female genitalia with paired concave sclerotizations on A7 sternite are also unique to <i>Niveas</i> .	<i>N. kone</i> can be separated from all other known choreutids based on its wing pattern (Fig. 1). Superficially, it is similar to a few species of <i>Breithia</i> and <i>Litobenthia</i> owing to its background color, but it lacks iridescent spots along forewing termen, which are always present in those two genera. Both male and female genitalia are very distinct from those of other choreutids (Figs 7, 8).	<i>N. agassizi</i> can be separated from other known choreutids by the wing pattern (Fig. 3). It is superficially similar to some species of <i>Choreutis</i> , but the latter usually have forewings with apparent patterning, and this is absent in <i>N. agassizi</i> . Female genitalia are very distinct from those of other choreutids (Fig. 9).
Description	Figs 1–9.	Figs 1, 2, 5, 7, 8.	Male unknown. Figs 3, 4, 6, 9.
Head	Labial palpi with projecting ventral scale tufts (Figs 2, 4).	Fig. 2.	Fig. 4.
Wings	Forewing veins R four-branched in <i>N. kone</i> (Fig. 5), five-branched in <i>N. agassizi</i> (Fig. 6), with $R_4$ and $R_5$ fused in basal 3/5; CuP present at termen for 1/3 to 1/5 wing length, extending as fold further towards base. Hindwing ten-veined, with $M_2$ in close proximity to the basally fused $M_3$ and $CuA_1$ ( <i>N. agassizi</i> ) or nine-veined, apparently with $M_3$ and $CuA_1$ completely fused into a single vein (Figs 5, 6).	Fore- and hindwing with brown background color, speckled with white-tipped scales in an irregular pattern; a distinct black band along termen of both wings within which are more or less equidistant white spots (Fig. 1).	Forewing bronze-brown with speckled white-tipped scales over most of its surface; distinct dark brown to black band along termen with two small white spots at apex; hindwing light brown (Fig. 3).

Taxon	<i>Niveus</i> Rota, gen. n.	<i>Niveus kone</i> Rota, sp. n.	<i>Niveus agassizi</i> Rota, sp. n.
Male genitalia	Tegumen rounded on top, tuba analis extending beyond tegumen; vinculum as inverted trapezoid ventrally emarginate; valva with costal margin straight; ventral margin rounded, ending with a horn-like projection; phallus twice as long as valva (Fig. 7).	As for the genus (Fig. 7).	Unknown.
Female genitalia	Apophyses anteriores slightly longer than posteriores; ostium bursae on A7 with a more or less strongly sclerotized antrum; ductus bursae straight, not coiled, with strong lateral sclerotizations; corpus bursae as a single sac ( <i>N. agassizi</i> ) or divided into two sacs ( <i>N. kone</i> ) with one or more signa. A7 sternite with paired, somewhat rounded, concave sclerotizations proximally, clearly visible in <i>N. kone</i> (Fig. 8), and slightly less so in <i>N. agassizi</i> (Fig. 9).	Corpus bursae split into two sacs; one sac with a V-shaped signum, the other with two round signa (Fig. 8).	Ductus bursae short and wide, opening into large corpus bursae, with one oval signum (Fig. 9).
Immature stages		Fig. 12. See a brief note in text.	Unknown.
Host plants	Genus <i>Ficus</i> (Moraceae).	<i>Ficus boryoarpa</i> Miq., <i>F. modosa</i> Teijsm. & Binn., <i>F. phaeocyste</i> K. Schum. & Lauterb., <i>F. pungens</i> Reinw. ex Blume, <i>F. variegata</i> Blume, and <i>F. uvasa</i> Roxb. (Moraceae).	Unknown.
Etymology	The generic name is derived from Latin <i>niveum</i> , meaning snowy, in reference to speckles of white-tipped scales in the wings of the type species; it is not treated as a Latin word and is feminine in gender.	The species is named after the Finnish Kone Foundation (Koneen Säätiö) in appreciation of their funding of this work. The name is a noun in apposition.	This species is named after David Agassiz, who collected all the known specimens and made many significant contributions to our knowledge of African micro-moths. The name is a noun in the genitive case.
