Abstract

The phylline plant bug genus *Tytthus* Fieber, previously containing 19 species, is revised. *Isoproba* Osborn and Drake, 1915, incorrectly placed in the subfamily Bryocorinae, tribe Dicyphini, is synonymized as a junior synonym of *Tytthus* Fieber, **syn. n.**; the only included species, *Isoproba picea* Osborn and Drake is transferred to *Tytthus*, **comb. n.**, as the senior synonym of *T. hondurensis* Carvalho, **syn. n.**; and *T. koreanus* Josifov and Kerzhner, 1972 is synonymized with *T. chinensis* (Stål 1860), **syn. n.**; and a lectotype for *T. parviceps* is designated. The six new species *T. femoralis* from Cuba, Ecuador, Guatemala, Jamaica, Mexico, and Peru, *T. fuscicornis* from New Mexico (USA), *T. mexicanus* from Mexico, *T. pallidus* from Brazil and Panama, *T. uniformis* from Arizona and New Mexico (USA), and *T. wheeleri* from the eastern United States are described, bringing the total number of species for the genus to 24. A color adult habitus illustration of *T. wheeleri*, color photographs for each species (except *T. juturnaiba* Carvalho and Wallerstein), illustrations of male genitalia, scanning electron photomicrographs of selected structures of certain species, and an identification key are provided to facilitate species recognition. A phylogenetic analysis is offered to help infer relationships.

Introduction

Members of the phyline plant bug genus *Tytthus* Fieber (1864) specialize in feeding on delphacid planthopper eggs, making them of great importance on agricultural monocots, such as rice and sugarcane, where Delphacidae are especially destructive (Wheeler 2001). The introduction of the South-Pacific *T. mundulus* (Breddin) into Hawaii (Muir 1920) that prevented the destruction of the Hawaiian sugarcane crop by the sugarcane delphacid, *Perkinsiella saccharicida* Kirkaldy, represents one of the classic examples of successful biological control (Zimmerman 1948).

Prior to this study, 19 species of *Tytthus* were recognized worldwide. Of these, 16 occur in the New World, including two Holarctic and one circumtropical species (Afrotropical, Neotropical, and southern Oriental). Three additional species are known from eastern and southeastern Asia, Australia, and the Indo-Pacific. *Tytthus* was long confused with and considered a junior synonym of the remarkably similar-appearing orthotyline genus *Cyrtorhinus* Fieber, 1858 (Reuter 1875c), until Carvalho and Southwood (1955) showed that the genus belonged in the subfamily Phylinae based on pretarsal structures and male genitalia.

Schuh (1974) included *Tytthus* in his new tribe Leucophoropterini, a group of predominately African, Australian, and South-Pacific taxa, based on the hairlike parempodia, the U-shaped endosoma, the relative small size of the male genitalia, the shape of the right paramere, and the simple female posterior wall. He also noted that *Tytthus* was not ant mimetic as are most other leucophoropterines. Kerzhner and Josifov (1999), however, conservatively placed Leucophoropterini in synonymy under Phylini after indicating that they were following Linnavuouri (1993), who thought it premature to split the tribe. Schuh (1995), however, maintains Leucophoropterini in the online version of his world mirid catalog (<http://research.amnh.org/pbi/catalog/>), until more information on relationships becomes available. More recently, Menard (2011) and Menard and Schuh (2011) gave convincing molecular and morphological evidence supporting the monophyly of Leucophoropterini, but also showed that *Tytthus* consistently grouped outside the tribe. As a consequence, I follow Menard (2011) and Menard and Schuh (2011) in transferring *Tytthus* from Leucophoropterini to nominate tribe Phylini.

In this paper, I revise the genus *Tytthus*; give a diagnosis and new host and distribution records for previously described species; synonymize the genus *Isoproba* Osborn and Drake as a junior synonym of *Tytthus* and transfer its only included species to *Tytthus* as the senior synonym of *T. hondurensis* Carvalho; and synonymize *T. koreanus* Josifov and Kerzhner under *T. parviceps* (Reuter). Six new New World species are described; 18 previously known species are redescribed; a revised identification key is provided to help distinguish the species of the genus; and a phylogenetic analysis is presented.

Methods

The male genital capsule was dissected and placed in room-temperature, 10% KOH solution for one to two days or until softened and cleared, after which it was rinsed in water and placed in a depression slide containing glycerol. The endosoma, right and left parameres, and phallosome were dissected and pencil sketched using a Nikon E400 compound microscope and drawing tube. Final illustrations were digitally rendered using Adobe Photoshop CS4.

Photomicrographs were taken using either an AMRAY 1810 or a Zeiss EVO/MA15 scanning electron microscope. Specimens were glued to standard SEM stubs, sputter coated, and examined at 6–10 KV.

Color images were captured using an EntoVision Imaging Suite that included a JVC KY-75 3CCD digital camera mounted to a Leica M16 zoom lens via a Leica z-step microscope stand. Multiple focal planes were merged using Cartograph 5.6.0 (Microvision Instruments, France) software. Plates of color habitus images (not to scale), SEM photomicrographs, and male genitalia were created using Adobe Photoshop CS4 and striped and numbered in Adobe Illustrator CS4.

Matrix code labels were attached to more than 1,000 specimens examined. These codes, referred to as unique specimen identifiers (USIs), are a way to uniquely identify specimens and are stored in a database developed for the NSF Planetary Biodiversity Project awarded to R. T. Schuh (American Museum of Natural History, New York, NY) and G. Cassis (University of New South Wales, Sydney, Australia). The full code contains the prefix “AMNH_PBI, an eight-digit number, and the specimen depository, for example (AMNH_PBI 00162206) (USNM).” USI codes are included in the specimen data listed at the end of each species treatment. To save space, the “AMNH_PBI” prefix has been omitted. Data for several hundred additional specimens also were recorded, but matrix code labels were not available for these collections (e.g., BMNH, NMW) at the time the data were captured and, thus, were not entered into the database and therefore lack USI numbers.

Specimen measurements were taken as follows: Length (dorsal length from apex of clypeus to posterior margin of hemelytral membrane); length to base of cuneus (dorsal length from apex of clypeus to base of cuneus); width across hemelytra (widest dorsal width across hemelytra, usually just above each cuneus); head length (lateral length from posterior margin of pronotum to apex of clypeus); head width (dorsal width across eyes); interocular width (greatest dorsal width between eyes); labium (length from a base of labrum to apex of segment IV); antennal segment length (self explanatory); pronotum length (dorsal median length); pronotum basal width (dorsal width across posterior margin). I follow Cassis (2008) in using the term “endosoma” rather than “vesica” for the male intromittent organ. Other terminology follows conventional use in the contemporary literature, as defined in Nichols (1989).

The phylogenetic analysis was performed using Winclada (Nixon 1999–2002), implementing the island hopping or the ratchet function to run NONA (Goloboff 1999) and TNT (Goloboff et al. 2008) using the traditional and random addition sequence functions. All cladograms were generated using Winclada.

Plant names follow the International Plant Names Index (2011) and the National PLANTS Database (USDA, NRCS, 2011).

Abbreviations and curators for collections cited in the paper are as follows:

AMNH	(American Museum of Natural History, New York; R. T. Schuh);

Species are arranged alphabetically in the text.

Taxonomy

Tytthus Fieber

<http://species-id.net/wiki/Tytthus>

Tytthus Fieber 1864: 82. Type species: *Capsus geminus* Flor, 1860. Designated by Kirkaldy 1906: 128.

Cylloceps Uhler, 1893: 711. Type species: *Cylloceps pellicia* Uhler, 1893. Monotypic. Synonymized by Carvalho and Southwood 1955: 17.

Periscopopus Breddin 1896: 106. Type species: *Periscopopus mundulus* Breddin, 1896. Monotypic. Preoccupied by *Periscopopus* Fitzinger, 1843 (Reptilia); synonymized by Carvalho and Southwood 1955: 17.

Breddiniessa Kirkaldy 1903: 13. New name for *Periscopopus* Breddin, 1896; synonymized by Carvalho and Southwood 1955: 17.

Isopropa Osborn and Drake 1915: 533. Type species: *Isopropa picea* Osborn and Drake, 1915. Monotypic. syn. n.

Diagnosis. Species of *Tytthus* are characterized by the small size (lengths ranging from 1.08 mm in brachypterous males of *T. wheeleri* to more than 3.60 mm in *T. mundulus*), the relatively broad to nearly round head, usually with a pale yellow spot on the vertex bordering the inner margin of each eye; slightly protruding eyes not touching the anterior margin of the pronotum; smooth, shiny, trapeziform to campanulate pronotum, with lateral margins straight to weakly concave and moderately to strongly flared humeral angles; flat to weakly raised calli; subparallel hemelytra, often brachypterous or abbreviated, with the membrane and cuneus greatly reduced; slender claws with setiform parempodia; slender, tapered abdomen; small genital capsule; simple, C- to weakly S-shaped endosoma, lacking a secondary gonopore; mitt-shaped left paramere; and simple, round to elongate-oval right paramere.

Description. Elongate subparallel to elongate oval species. Head shiny, impunctate, broader than long, sometimes becoming broadly rounded, especially in males, always slightly wider than anterior margin of pronotum; eyes prominent, more so in males, finely granulate, usually with scattered, fine, short setae; in dorsal view, frons and clypeus weakly rounded to prominent and pointed anteriorly; interocular space proportionately narrower in males (because of more prominent eyes) than females, nearly always with a small to large yellow or pale spot adjacent to inner margin of each eye; posterior margin nearly straight, with eyes nearly touching anterior margin of pronotum, to sometimes more narrowed behind eyes forming a necklike area more distinctly separating eyes from pronotum. Labium extending from bases of hind coxae to well onto abdomen near segment III or IV; segment I extending from base of head to bases of forecoxae. Antennal segment I shortest, stoutest; segment II longest; segment III longer than to subequal to segment IV. Pronotum shiny, impunctate, calli usually prominent, often with a glaucous sheen; subrectangular to trapeziform, especially in flightless brachypters, to strongly campanulate or bell-shaped in macropters. Mesoscutum broadly exposed in macropters; concealed by posterior margin of pronotum in brachypters. Scutellum well developed, equilateral. Hemelytra translucent, opaque white to bicolored with dark clouds, transverse bands, or extensive dark areas; macropterous or brachypterous, if only one sex brachypterous, always the female; fully macropterous hemelytra with each cuneus entire and membrane fully developed, extending well beyond apex of abdomen; brachypterous hemelytra (see discussion on brachyptery) abbreviated, ranging from a partially shortened membrane, extending only to apex of abdomen, to a strongly abbreviated membrane represented by only a remnant fringe on posterior edge of coleopteriform corium and clavus, with cuneus absent; in most extreme forms, only short hemelytral pads present, entirely lacking the cuneus and membrane, and extending only to abdominal terga III or IV. Lengths range in macropterous males from 2.14–3.42 mm; brachypterous males 1.08–1.28 mm; macropterous females 1.80–3.52 mm; and

Figure 1. *Tytthus wheeleri*, sp. n., adult brachypterous ♂.

brachypterous females 1.44–1.68 mm. Ventral surface shiny, impunctate. Ostiolar evaporative area with a prominent auricle, curving posteriorly, gland opening large and distinct. Legs slender; femora unspotted, sometimes infuscated; tibiae slender, with or without distinct spines; tarsi slender, lengths of segment II and III subequal; claws elongate, slender, parempodia setiform.

Male genitalia: Endosoma relatively simple C-shaped to S-shaped, composed of a single, simple tube, often distally truncate or concave, lacking an apparent secondary gonopore. Left paramere mitt-shaped, with two arms and a narrow basal stem; right arm longest, widest, and most prominent, distally acute to rounded, gradually narrowing from base to apex, often broadened just before apex; left arm much shorter, distally acute. Right paramere elongate oval to nearly round, with a short basal stem. Phallosome simple, sheathlike, exposed apex gradually narrowing from base to an acute apex.

Discussion. Members of this genus are so superficially similar to species of the orthotyline genus *Cyrtorhinus* that Reuter (1875c) placed *Tytthus*, in synonymy under it, where it remained for the next 80 years. Even H. H. Knight (1923, 1925, 1931), North America's most knowledgeable and prolific mirid specialist, failed to recognize the misplacement, and R. L. Usinger (1939), who treated several South Pacific species of *Tytthus* noted "An apparent structural anomaly in *Cyrtorhinus* which has not been given sufficient attention is the absence, in certain species, of arolia between the claws. The presence or absence and form of the arolia is usually a very reliable guide to relationships in Miridae." Despite the character differences between these taxa, the species remained together under *Cyrtorhinus* until Carvalho and Southwood (1955) documented the obvious differences in male genitalia and pretarsal structure.

Another problematic genus, *Isoproba* Osborn and Drake (1915), has not been mentioned in the primary literature since its original description. Described to accommodate the only included species, *I. picea* Osborn and Drake from Guatemala, it was said to be "readily separated from the [orthotyline] genus *Paraproba* Distant and allied genera by the more globose head and the peculiar shape of the thorax (Osborn and Drake 1915)." Carvalho (1952, 1958), however, without explanation, transferred it to the tribe Dicyphini (then placed it in the subfamily Phylinae), whose members also have generally rounded heads, as well as setiform parempodia. Cassis (1984) noted that he was unable to locate the holotype and, therefore, left it in Dicyphini with "considerable reservation."

I have studied the holotype of *I. picea* deposited in the Ohio State University collection and, like most species included in the genus *Tytthus*, it has an overall shiny, fuscous to black head, pronotum, and scutellum, pale translucent hemelytra, and slender legs and antennae. The male genitalia are of the same type as for other species of *Tytthus*. The left paramere is mitt-shaped, the right paramere is relatively small, elongate oval, and simple, and the endosoma is slender and C-shaped. *Isoproba picea* differs from other species of *Tytthus* only in having a more distinctly rounded or bulbous head that is narrowed posteriorly into a short neck, especially in males, and the shallowly convex eyes hardly protruding from the side of the head. In addition, I have discovered that *T. hondurensis* Carvalho (1984) is a junior synonym of *T. piceus*. As a consequence, *Isoproba* is placed as a junior synonym of *Tytthus*.

Wing polymorphism: Slater (1975) separated the various types of wing modifications in the family Lygaeidae (sensu lato) into seven main categories: 1) Aptery (wings entirely absent); 2) Microptery (wings reduced to widely separated pads); 3), Staphylinoidy (wings have the clavus and corium indistinguishably fused into a coriaceous pad, and the wings meet evenly along the midline for their entire length, and usually

cover only the first three abdominal segments); 4, Coleoptery (wings may or may not be reduced, but the coriaceous portion is not reduced but lengthened, the clavus and corium are fused, and the wings meet along the midline but do not overlap); 5) Brachyptery (clavus and corium either distinctly separate or fused, but shorter than in macropters, with only the inner portion of the membrane overlapping); 6) Submacroptery (clavus and corium always separate, with membrane slightly shortened, leaving the last abdominal segment exposed); and 7) Macroptery (wings unmodified, fully developed). Of the species of *Tytthus* exhibiting wing polymorphism, two can be categorized as staphylinoid (*T. alboornatus*, *T. wheeleri*), two as brachypterous (*T. montanus*, *T. piceus*), and four (*T. balli*, *T. fuscicornis*, *T. pubescens*, and *T. uniformis*) as submacropterous. The remaining sixteen species are known only from macropterous individuals.

Importance in biological control: It has been documented that most, if not all, species of *Tytthus* are specialized delphacid and, to a lesser extent, leafhopper egg predators. The best documented species, *T. mundulus*, provides a good example of successful classical biological control (Hagen and Franz 1973, van den Bosch and Messenger 1973, Rosen 1985, Wheeler 2001). Frederick Muir (1920) discovered while searching for predators of the sugarcane delphacid in Queensland, Australia, that nymphs and adults fed on delphacid eggs. As a consequence, he brought *T. mundulus* to Hawaii for release into the sugarcane fields. As Usinger (1939) noted, “Muir’s discovery that *Tytthus* (as *Cyrtorbinus*) *mundulus* (Breddin) lives exclusively on the eggs of the sugar-cane leafhopper, *Perkinsiella saccharicida* Kirkaldy, led to one of the most outstanding successes in the field of biological control of injurious insects.” Zimmerman (1948) summed up the importance of this bug by saying “This one bug has saved the Hawaiian sugar industry and the Territory millions of dollars—its true worth can hardly be estimated.”

Other species also have shown considerable potential in biological control. In South Africa, both *T. mundulus* and *T. parviceps* (Reuter) have been investigated for control of a tropiduchid, *Numicia viridis* Muir, on sugarcane (Carnegie and Harris 1969). Although *T. mundulus* was the better-known predator, *T. parviceps* was more easily reared and showed the greatest potential for controlling *N. viridis*. Jhansi et al. (2002) studied the biology and prey preferences of *T. parviceps* on planthoppers and leafhoppers on rice in India, including the brown planthopper, *Nilaparvata lugens* (Stål). The Holarctic species *T. pubescens* (Knight) and *T. pygmaeus* (Zetterstedt) are known to prey on leafhoppers and delphacids in England (Southwood and Leston 1959, Rothschild 1963, Wheeler and Henry 1992). In coastal eastern North America, Döbel and Denno (1994) considered *T. alboornatus* (Knight) and *T. vagus* (Knight) among the major predators of saltmarsh delphacids on two species of *Spartina* (Poaceae). For additional information on the hosts and habits of these predatory bugs, see the respective species within this revision.

Key to Species of *Tytthus*

- 1 Bases (or “knees”) of tibiae narrowly fuscous.....2
- Tibiae uniformly pale or dark, bases never fuscous.....6

- 2 Apex and base of antennal segment I narrowly pale yellow; ventral surface of antennal segment II in male with a row of short, erect, stiff setae (Fig. 59), in addition to thickly set semierect or recumbent setae.....3
- Apical fourth of antennal segment I pale yellow, remainder of segment black; ventral surface of antennal segment II in male with only semierect or recumbent setae.....4
- 3 Anterior half of pronotum mostly or entirely pale yellow; pale spot on vertex large and distinct (Figs 32, 34); distribution: circumtropical.....
..... *T. parviceps* (Reuter)
- Anterior half of pronotum uniformly dark or with only traces of pale yellow; pale spot on vertex small, indistinct (Figs 9, 10); distribution: southeastern Asia, Indo-Pacific, Australian *T. chinensis* (Stål)
- 4 Hind femur uniformly pale yellow; antennal segment II dark brown to fuscous, sometimes darker at base (Figs 19, 20); distribution: Mexico
..... *mexicanus* Henry, sp. n.
- Hind femur fuscous distally; antennal segment II dark or pale.....5
- 5 Hind femur fuscous on distal two thirds, basal third and apex narrowly pale; antennal segment II pale, with a fuscous band at base (Figs 13, 14); distribution: Mexico to Ecuador, and the West Indies.....*femorialis* Henry, sp. n.
- Hind femur fuscous on apical third; front and middle femora sometimes infuscated; antennal segment II uniformly fuscous (Fig. 12); distribution: Argentina.....*entrierianus* Carvalho & Carpintero
- 6 Antennal segment I mostly pale yellow to brownish yellow, at most narrowly dark at base.....7
- Antennal segment I mostly dark brown or black, at most pale at base and/or apex.....14
- 7 Antennal segment I pale, with a dark ring at base, if presence of ring indistinct, hemelytra extensively dark brown or fuscous, with base of clavus and corium pale or whitish (Fig. 28).....8
- Antennal segment I uniformly pale, without a dark ring at base, sometimes narrowly fuscous apically; hemelytra uniformly yellow, pale yellow invaded with dark brown areas, or dark smoky brown with costal margins paler (Figs 5, 24, 53).....12
- 8 Hemelytra largely fuscous to black, pale at base of clavus and corium only...9
- Hemelytra uniformly pale or whitish, at most with dark smoky brown shading.....10
- 9 Larger species, length greater than 2.65 mm in macropters; cuneus uniformly dark brown (Figs 21–23); distribution: Arizona, Montana, and Utah
..... *montanus* Carvalho & Southwood
- Smaller species, length less than 2.50 mm in macropters; cuneus pale or whitish, cuneus lacking in brachypters, apex of each hemelytron pale or white (Figs 2–4); distribution: coastal eastern North America.....
..... *alboornatus* (Knight)

- 10 Antennal segments II–IV intermixed with long, erect and semierect setae nearly as long as diameter of segment; posterior angles of pronotum often pale; hemelytra uniformly pale or translucent white (Figs 38, 39); distribution: Holarctic ***pubescens* (Knight)**
- Antennal segment II–IV with only short, recumbent setae much shorter than diameter of segment; pronotum always uniformly fuscous to black; hemelytra often clouded with smoky brown **11**
- 11 Head bulbous in both sexes; length of antennal segment I subequal to width of interocular space; pronotal calli prominent, with a distinct glaucous sheen (Figs 35–37); distribution: Mexico to Colombia, and Maryland to Florida in the eastern United States ***piceus* (Osborn & Drake)**
- Head not bulbous, much broader than long; length of antennal segment I greater than width of interocular space; pronotal calli less prominent and without obvious glaucous sheen (Figs 30, 31); distribution: Brazil and Panama ***pallidus* Henry, sp. n.**
- 12 Head and pronotum black; antennal segment II fuscous or black (Figs 24, 25); distribution: Indo-Pacific, Australia, introduced into Hawaii ***mundulus* (Breddin)**
- Head and pronotum entirely or extensively pale; antennal segment II pale yellowish brown **13**
- 13 Entirely pale or brownish yellow, including appendages (Figs 53, 53); distribution: central Pacific Region ***zwaluwenbergi* (Usinger)**
- Extensively pale or brownish yellow, but with brown mottling and marks on head, pronotum around calli, scutellum, cloud on apical area of corium, and undersurface of thorax and margins of abdomen (Figs 5, 6); distribution: Brazil and Peru ***amazonicus* Carvalho**
- 14 Antennal segment I fuscous to black, with apex and/or base pale or yellowish.. **15**
- Antennal segment I entirely fuscous to black **19**
- 15 Apex and basal one third of antennal segment I pale, leaving a broad fuscous or black band through middle (Figs 26, 27); distribution: widespread through Neotropics, and Florida in the United States ***neotropicalis* (Carvalho)**
- Only apex of antennal segment I pale, remainder dark **16**
- 16 Apical one fourth of antennal segment I pale (Figs 41–44); distribution: Holarctic ***pygmaeus* (Zetterstedt)**
- Apical one fifth or less of antennal segment I pale **17**
- 17 Antennal segment II pale yellowish brown; hemelytra uniformly pale; hind femur uniformly pale; distribution: Panama ***panamensis* Carvalho & Southwood**
- Antennal segment II fuscous; hemelytra dark smoky brown, especially through middle; hind femora variable **18**
- 18 Hind femur infuscated on apical third (Figs 48, 49); distribution: coastal eastern North America ***vagus* (Knight)**

- Hind femur uniformly pale yellow; distribution: Rio de Janeiro, Brazil.....
.....*juturnaiba* **Carvalho & Wallerstein**
- 19 Head black, contrasting with largely pale orange pronotum and scutellum,
pronotum sometimes becoming infuscated **20**
- Head, pronotum, and scutellum uniformly fuscous to black..... **22**
- 20 Tibiae, femora, and pronotum uniformly pale orange (Figs 45–47); distribu-
tion: Arizona and New Mexico *uniformis* **Henry, sp. n.**
- Tibiae fuscous to black; femora orange to orange brown, often infuscated
or streaked with red; pronotum pale orange to brown, usually invaded with
fuscous or dark brown..... **21**
- 21 Pronotum brown to orange brown, calli darker brown, with a narrow, trans-
verse, pale or white fascia across anterior margin; hemelytron uniformly pale,
smoky brown (Figs 17, 18); distribution: Arizona *insperatus* (**Knight**)
- Pronotum orange to orange brown, but lacking a narrow, transverse, pale
fascia across anterior margin; hemelytron pale with inner half of clavus, apical
half of corium, and apex of cuneus brown (Figs 7, 8); distribution: Florida to
Texas..... *balli* (**Knight**)
- 22 Hemelytra pale or translucent white; hind femora pale yellow (Figs 15, 16);
distribution: Arizona..... *fuscicornis* **Henry, sp. n.**
- Hemelytra largely dark brown to fuscous; hind femora fuscous to black ... **23**
- 23 Hemelytra with basal third of corium, basal half of clavus, and most of cu-
neus pale or white; antennal segment I black; all femora fuscous to black;
only macropterous male known (Fig. 11); distribution: Colombia.....
..... *columbiensis* **Carvalho**
- Hemelytra with basal third of corium and basal half of clavus pale; cuneus,
when present, uniformly dark brown; antennal segment I pale yellow; only
hind femur fuscous, front and middle femora yellowish; brachypters common
(Figs 50–52); distribution: eastern United States *wheeleri* **Henry, sp. n.**

***Tytthus alboornatus* (Knight)**

http://species-id.net/wiki/Tytthus_alboornatus

Figs 2–4, 109–112

Cyrtorhinus alboornatus Knight 1931: 172 (orig. descrip.).

Tytthus alboornatus: Carvalho and Southwood 1955: 27 (descrip., n. comb.); Carvalho 1958: 156 (cat.); Henry and Wheeler 1988: 457 (cat.); Schuh 1995 (cat.); Denno 1983: 702 (note); Hoffman 2000: 24 (note, distr.); Hines et al. 2005: 264 (note).

Diagnosis. This species is distinguished by the small size, usually brachypterous heme-lytra, overall dark brown coloration, with the basal third to half of the corium and cla-vus, and cuneus (or in brachypters the posterior margin of the corium) pale or white, the pale yellowish brown antennal segment I, the mostly dark brown femora and pale

yellowish-brown tibiae and tarsi. Macropterous and brachypterous forms are known for both sexes.

This species is most similar in size and coloration to *T. wheeleri*, sp. n. In *T. alboornatus*, antennal segment I is pale yellowish brown and the posterior margin of each hemelytron in brachypters or the cuneus in macropters is pale or white, whereas in *T. wheeleri*, antennal segment I is dark brown and the posterior margin of each hemelytron in brachypters and or cuneus in macropters is uniformly dark brown.

Description. *Macropterous male* (n = 1, plus holotype in parentheses) (Fig. 2): Length to apex of hemelytron 2.21 mm (2.24 mm), length to base of cuneus 1.57 mm (1.66 mm), width across hemelytra 0.72 mm (0.77 mm). *Head*: Length 0.72 mm (0.26 mm), width across eyes 0.51 mm (0.54 mm), interocular width 0.30 mm (0.30 mm). *Labium*: Length [embedded in glue] (0.94 mm). *Antenna*: Segment I length 0.29 mm (0.37 mm), II 0.88 mm (1.06 mm), III 0.59 mm (0.72 mm), IV 0.48 mm (missing). *Pronotum*: Length 0.32 mm (0.35 mm), basal width 0.45 (0.72 mm).

Brachypterous male (n = 5): Length to apex of abdomen 1.34–1.57 mm, length to base of hemelytron (cuneus and membrane absent) 1.15–1.41 mm, width across hemelytra 0.58–0.62 mm. *Head*: Length 0.22–0.26 mm, width across eyes 0.50–0.59 mm, interocular width 0.29–0.30 mm. *Labium*: Length 0.83–0.86 mm. *Antenna*: Segment I length 0.29–0.30 mm, II 0.80–0.86 mm, III 0.53–0.64 mm, IV 0.45–0.61 mm. *Pronotum*: Length 0.24–0.29 mm, basal width 0.54–0.56 mm.

Coloration: *Head*: Brown to dark brown, with a small, vague, pale spot near inner margin of each eye; eyes dark brown to reddish brown. *Labium*: Yellowish brown, apex of segment IV darker brown. *Antenna*: Segment I pale yellowish brown; segments II–IV yellowish brown, sometimes becoming slightly darker brown. *Pronotum*: Uniformly shiny brown to very dark brown or fuscous. *Mesoscutum*: Hidden under base of pronotum in brachypters, narrowly exposed in macropters. *Scutellum*: Brown to dark brown, with apex pale. *Hemelytron*: Broadly dark brown, with basal one fourth and narrow apex or cuneus (in macropter) pale or white; membrane on only macropter fully developed, smokey brown. *Ventral surface*: Thoracic pleural areas brown to dark brown, ventral surface sometime paler yellowish brown; abdomen dark brown to fuscous, especially laterally, ventral area sometimes paler yellowish brown. *Ostiole evaporative area*: Dark brown. *Legs*: Coxae pale yellowish brown to whitish, with bases dark brown; femora dark brown, pale yellowish brown at bases and apices; tibiae, tarsi, and claws pale yellowish brown.

Structure, texture, and vestiture: *Head*: Shiny, impunctate; broader than long, rounded anteriorly, truncate basally; set with short, recumbent, nearly bristlelike setae on vertex and frons. *Labium*: Extending beyond metacoxae to second or third abdominal segment. *Pronotum*: Shiny, impunctate, nearly rectangular, wider than long, anterior angles rounded, base truncate, calli indistinct, not differentiated from discal surface, only slightly raised and rounded; set with scattered, recumbent, brown to nearly black setae. *Scutellum*: Equilateral, impunctate, with a few scattered, short, recumbent setae. *Hemelytron*: Macropter with fully developed cuneus and membrane, including two closed cells or areoles; all other specimens (except one macropter) brachypterous

(staphylinoid), with clavus fused (and claval suture absent) with corium, cuneal fracture and cuneus absent, and membrane absent or rarely with only a remnant narrow strip along truncate posterior margin, extending from about abdominal tergite IV to nearly to apex of abdomen; set with evenly scattered, short, recumbent brown setae.

Male genitalia: *Left paramere* (Fig. 109): Mitt-shaped; right arm long, stout; left arm short, apically acute. *Right paramere* (Fig. 110): Oval. *Endosoma* (Fig. 111): Slender, S-shaped, apex pointed. *Phallosome* (Fig. 112): Relatively slender, apically acute.

Macropterous female (n = 1) (Fig. 3): Length to apex of hemelytron 2.45 mm, length to base of cuneus 1.85 mm, width across hemelytra 0.93 mm. *Head:* Length 0.32 mm, width across eyes 0.58 mm, interocular width 0.32 mm. *Labium:* Length 0.99 mm. *Antenna:* Segment I length 0.32 mm, II 0.91 mm, III 0.69 mm, IV 0.67 mm. *Pronotum:* Length 0.37 mm, basal width 0.86 mm.

Brachypterous "minor" female [see discussion below] (n = 10): Length to apex of abdomen 1.44–1.79 mm, length to apex of hemelytra 1.34–1.60 mm, width across hemelytra 0.58–0.80 mm. *Head:* Length 0.26 mm, width across eyes 0.43–0.53 mm, interocular width 0.29–0.30 mm. *Labium:* Length 0.80–0.91 mm. *Antenna:* Segment I length 0.26–0.27 mm, II 0.74–0.80 mm, III 0.53–0.59 mm, IV 0.48–0.61 mm. *Pronotum:* Length 0.27–0.29 mm, basal width 0.50–0.56 mm.

Brachypterous "major" female (n = 2) (Fig. 4): Length to apex of abdomen 2.02–2.30 mm, length to apex of hemelytra 1.60–1.86 mm, width across hemelytra 0.93–0.99 mm. *Head:* Length 0.27–0.30 mm, width across eyes 0.56–0.61 mm, interocular width 0.34–0.35 mm. *Labium:* Length 0.91–0.96 mm. *Antenna:* Segment I 0.30–0.32 mm, II 0.90–0.96 mm, III 0.64 mm, IV 0.50 mm. *Pronotum:* Length 0.29–0.34 mm, basal width 0.59–0.64 mm.

Hosts. Taken by A. G. Wheeler on inland saltgrass, *Distichlis spicata* (L.) Green [Poaceae]; saltmeadow cordgrass, *Spartina patens* (Ait.) Muhl.; and sand cordgrass, *Spartina bakeri* Merr. [Poaceae]. Denno (in litt, 2005) informed me that *T. alboornatus* was extremely abundant only in *Spartina patens* in Tuckerton, New Jersey, but not in *S. alterniflora* where *T. vagus* was restricted. Denno (1983) and Hines et al. (2005) reported that *T. alboornatus* preys on eggs of the delphacids *Tumidagena minuta* McDermott and possibly *Delphacodes detecta* (Van Duzee) in *S. patens*.

Distribution. Previously known only from Florida, New Jersey, New York, and Virginia (Henry and Wheeler 1988, Hoffman 2000). New U. S. state records are Connecticut, Louisiana, South Carolina, and Texas. This distribution indicates that *T. alboornatus* should occur in all coastal states from at least New England to Texas.

Discussion. *Tytthus alboornatus* (Figs 2–4) is one of the smallest species in the genus, second in size only to the similar-appearing *T. wheeleri* (Figs 50–52). Like *T. wheeleri*, macropterous forms of this species are extremely uncommon or rare. Of the more than 50 specimens studied, I have found only two macropterous males, including the holotype (from Florida) and three macropterous females (from Connecticut and South Carolina).

In addition, populations include what I call "minor" and "major" females. Along the Connecticut and New Jersey coasts, specimens are much smaller (shorter and more

Wheeler, Jr., USNM) **53** *T. zwaluwenburgi*, macropterous ♂ (Canton Island, 20 Nov. 1940, R. Danner, BPBM) **54** *T. zwaluwenburgi*, macropterous ♀ (Baker Island, 18 April 1935, E. H. Bryan, BPBM).

slender), whereas farther south in South Carolina and Florida several specimens are considerably larger, with more well-developed pronota and hemelytra. Two macropterous females from Connecticut also were smaller than the macropter from South Carolina. This size difference may simply be due to more harsh or crowded conditions, with a more limited food supply versus smaller populations with more plentiful prey available, rather than their north/south distributions. More work is needed to better understand the factors that influence size.

Type material examined. Holotype ♂ (00162206) (USNM): **UNITED STATES: Florida: Duval Co.:** Jacksonville, 30.33194°N, 81.65583°W, 23 Jul 1926, E. D. Ball.

A. Buhlmann, 1 ♂ (VMNH).

***Tytthus amazonicus* Carvalho**

http://species-id.net/wiki/Tytthus_amazonicus

Figs 5, 6, 113–116

Tytthus amazonicus Carvalho 1983: 191 (orig. descrip.); Schuh 1995: 248 (cat.).

Diagnosis. This species, distinguished by the pale antennae and legs, mostly pale dorsum, with only the frons and basal margin of the head, scutellum, inner margin of the clavus, and the distal third of the corium brown, cannot be easily confused with any other species of the genus. Only macropters are known.

Tytthus amazonicus keys to *T. zwaluwenbergi* because of the pale tibiae, antennae, and head but its relationship with this central Pacific species almost certainly is only superficial. *Tytthus amazonicus* is readily separated by the pale head and pronotum invaded with dark brown, the largely pale hemelytra with the inner half of each clavus and the apical half of each corium dark brown, whereas *T. zwaluwenbergi* is uniformly pale yellowish brown.

Description. *Male* (n = 5) (Fig. 5): Length to apex of hemelytron 2.83–2.93 mm, length to base of cuneus 2.00–2.10 mm, width across hemelytra 0.86–0.93 mm. *Head*: Length 0.34–0.37 mm, width across eyes 0.62–0.64 mm, interocular width 0.29–0.30 mm. *Labium*: Length 1.22–1.28 mm. *Antenna*: Segment I length 0.37–0.38 mm, II 1.00–1.08 mm, III 0.56–0.66 mm, IV 0.48–0.53 mm. *Pronotum*: Length 0.35–0.38 mm, basal width 0.83–0.88 mm.

Coloration: *Head*: Pale yellowish brown dorsally, dark brown ventrally, on frons, and narrowly across basal margin; eyes dark brown to reddish brown. *Labium*: Pale yellowish brown. *Antenna*: Segments I–III uniformly pale yellow to yellowish brown, segment I sometimes darker brown through middle with apex and base pale, segment IV slightly darker brown. *Pronotum*: Mostly pale yellowish brown, collar and narrow posterior margin around calli darker brown, entire discal area darker brown on some specimens. *Mesoscutum*: Pale yellowish brown, tinged with darker brown through middle. *Scutellum*: Brown. *Hemelytron*: Predominantly pale or pale yellowish brown, with inner margin of clavus and apical half of corium darker brown; cuneus uniformly pale or pale yellowish brown; membrane translucent brown, veins darker brown. *Ostiolar evaporative area*: Dark brown. *Ventral surface*: Thoracic area dark brown; abdomen brown to yellowish brown, darker brown along lateral margins and genital capsule. *Legs*: Coxae pale yellow, meso- and metacoxae brown at bases; remainder of legs pale yellow.

Structure, texture, and vestiture: *Head*: Wider than long, impunctate, frons with a glaucous sheen; buccula relatively wide; set with short recumbent setae on frons and a few longer, more erect setae on vertex. *Labium*: Extending beyond metacoxae to base of abdomen; segment I extending to middle of procoxae. *Pronotum*: Impunctate, shiny; trapeziform, anterior angles rounded, lateral margins weakly concave, basal angles flared wider, basal margin concave; calli weakly swollen, delimited posteriorly by a shallow impressed line; set with evenly scattered, short, recumbent setae. *Mesoscutum*: Broadly exposed. *Scutellum*: Impunctate, equilateral, with scattered, short,

recumbent setae. *Hemelytron*: Macropterous, impunctate, shiny lateral margins sub-parallel, cuneus longer than wide at base, membrane with two areoles, extending well beyond abdomen.

Male genitalia: *Left paramere* (Fig. 113): Mitt-shaped, with a long, broad right arm and shorter, more slender left arm. *Right paramere* (Fig. 114): Elongate oval. *Endosoma* (Fig. 115): S-shaped, with apex rounded. *Phallosome* (Fig. 116): Relatively slender, apically acute.

Female (n = 4) (Fig. 6): Length to apex of hemelytron 2.98–3.14 mm, length to base of cuneus 2.18–2.30 mm, width across hemelytra 0.91–1.07 mm. *Head*: Length 0.34–0.35 mm, width across eyes 0.58–0.59 mm, interocular width 0.30–0.32 mm. *Labium*: Length 1.23–1.33 mm. *Antenna*: Segment I 0.29–0.30 length mm, II 0.85–0.91 mm, III 0.56–0.61 mm, IV mm. *Pronotum*: Length 0.42–0.43 mm, basal width 0.83–0.96 mm.

Host. Unknown. Most specimens taken at light.

Distribution. Described and previously known only from Amazonas, Brazil. Peru is a new country record.

Specimens examined. **BRAZIL: Amazonas:** Reserva Ducke, 25 km NNE of Manaus, 120 m, 26 Jul 1973, R.T. Schuh, 2 ♂♂ (00165859, 00165860), 2 ♀♀ (00165857, 00165858) (AMNH), 1 ♂ (00162159), 1 ♀ (00162158) (USNM). On Amazon River, Jul 1900, Boquaert, 1 ♂ (00161884) (USNM). R. Madeira to St. Antonio, May 74, 3 ♀♀ (BNHM). **Para: Santarem Co.:** Taperinha, 11 Jun 1927 - 20 Jun 1927, Zerny, 1 ♂ (00161615) (USNM). **PERU: Junin:** Satipo, 11.2667°S, 74.6833°W, Jul 1940 - Aug 1940, P. Paprzycki, 1 ♀ (00161613) (USNM). **Loreto:** Lake Yarinacocha, 10 km NW of Pucallpa, 150 m, 10 Dec 1971, R. T. Schuh, 1 ♂ (00165855), 1 ♀ (00165856) (USNM).

Tytthus balli (Knight)

http://species-id.net/wiki/Tytthus_balli

Figs 7, 8, 117–120

Cyrtorhinus balli Knight 1931: 171 (orig. descrip.).

Tytthus balli: Carvalho and Southwood 1955: 30 (descrip., n. comb.); Carvalho 1958: 157 (cat.); Henry and Wheeler 1988: 457 (cat.); Schuh 1995: 248 (cat.).

Diagnosis. This species is distinguished by the black head and antennae, orange-brown pronotum often infuscated laterally, orange-brown scutellum, pallid hemelytra infuscated along inner margin of clavus and distal third of corium, orange-brown femora, and dark brown to fuscous tibiae. All known males are macropterous; both macropterous and brachypterous females occur.

Tytthus balli is very similar to *T. insperatus* and *T. uniformis* based on the black head and antennal segments I and II, and the orange to brownish-orange pronotum and femora. From *T. insperatus*, it is distinguished by the uniformly brownish-orange pronotum lacking a pale anterior margin and the infuscated apical half of each

corium. From *T. uniformis* it is distinguished by the fuscous tibiae and infuscated hemelytra.

Description. *Macropterous male* (n = 5, plus holotype in parentheses) (Fig. 7): Length to apex of hemelytron 2.58–2.73 mm (2.68 mm), length to base of cuneus 1.85–1.88 mm (1.96 mm), width across hemelytra 0.70–0.83 mm (0.80 mm). *Head*: Length 0.34–0.35 mm (0.37 mm), width across eye 0.58–0.59 mm (0.59 mm), interocular width 0.30–0.32 (0.30 mm). *Labium*: Length 1.05–1.07 mm (1.02 mm). *Antenna*: Segment I length 0.30–0.32 mm (0.29 mm), II 0.98–1.07 mm (1.02 mm), III 0.69–0.85 mm (0.80 mm), IV 0.48–0.51 mm (missing). *Pronotum*: Length 0.30–0.32 mm (0.34 mm), basal width 0.72–0.74 mm (0.69 mm).

Coloration: *Head*: Uniformly shiny black, with a distinct, yellow spot on inner interocular area bordering each eye. *Labium*: Yellowish brown, apex of segment IV fuscous. *Antenna*: Uniformly black. *Pronotum*: Uniformly orange to darker brownish orange, often becoming infuscated laterally and around calli. *Mesoscutum*: Orange to brownish orange. *Scutellum*: Dark orange or brownish orange to dark brown. *Hemelytron*: Pale or whitish on basal half and narrow apical margin of corium, narrow outer margin of clavus, and basal half of cuneus, dark brown on most of clavus, apical half of corium, and apex of cuneus; membrane translucent brown, veins slightly dark brown. *Ostiole area*: Brownish orange to fuscous. *Ventral surface*: Thoracic area orange to dark brownish orange; abdomen brownish orange to dark brown, often becoming fuscous laterally, genital capsule dark brown to fuscous. *Legs*: Coxae pale or whitish, orange to dark brownish orange basally; femora orange to brownish orange; tibiae brown on palest specimens, especially protibia, to dark brown or black on darker individuals; tarsi and claws brown to dark brown.

Structure, texture, and vestiture: *Head*: Broader than long, shiny, impunctate; sparsely set with short, recumbent setae; buccula relative wide, tapering posteriorly. *Labium*: Extending to apices of metacoxae or base of abdomen; segment I extending only to prosternum. *Pronotum*: Impunctate, shiny; trapeziform, anterior angles rounded, lateral margins weakly concave, basal angles flared wider, basal margin concave; calli weakly swollen, delimited posteriorly by a shallow impressed line; set with evenly scattered, short, recumbent setae. *Mesoscutum*: Broadly exposed. *Scutellum*: Impunctate, equilateral, width a few scattered, recumbent setae. *Hemelytron*: Macropterous, impunctate, shiny, lateral margins subparallel, cuneus longer than wide at base, membrane with two areoles, extending well beyond abdomen.

Male genitalia: *Left paramere* (Fig. 117): Mitt-shaped; right arm long, broad; left arm shorter, more slender. *Right paramere* (Fig. 118): Oval. *Endosoma* (Fig. 119): C-shaped. *Phallosome* (Fig. 120): Slender, relatively straight, apically acute.

Macropterous female (n = 2): Length to apex of hemelytron 2.90–3.07 mm, length to base of cuneus 2.08–2.28 mm, width across hemelytra 0.83–0.93 mm. *Head*: Length 0.34–0.35 mm, width across eyes 0.58–0.61 mm, interocular width 0.32–0.34 mm. *Labium*: Length 1.17–1.22 mm. *Antenna*: Segment I length 0.27–0.32 mm, II 1.02–1.118 mm, III 0.77–0.80 mm, IV 0.48–0.54 mm. *Pronotum*: Length 0.32–0.34 mm, basal width 0.74–0.78 mm. Similar to males in color and shape.

Brachypterus female (n = 4) (Fig. 8): Length to apex of abdomen 2.20–2.38 mm, length to base of cuneus 1.88–1.93 mm, width across hemelytra 0.86–0.90 mm. *Head*: Length 0.37–0.40 mm, width across eyes 0.58–0.59 mm, interocular width 0.34–0.35 mm. *Labium*: Length 1.17–1.20 mm. *Antenna*: Segment I length 0.27–0.29 mm, II 1.01–1.02 mm, III 0.77–0.80 mm, IV 0.48–0.50 mm. *Pronotum*: Length 0.30–0.32 mm, basal width 0.67–0.69 mm. Similar to males in color, differing in having the cuneus reduced (basal width subequal to length) and the membrane shortened (with the veins absent or indistinct), extending only to the middle of the last abdominal tergite.

Hosts. Previously recorded only from imported roses (Carvalho and Southwood 1955), which undoubtedly is an incidental record. A. G. Wheeler and I have swept specimens from a salt marsh area containing mixed herbaceous vegetation and *Spartina* sp. [Poaceae].

Distribution. This species was described from Jacksonville, Florida (Knight 1931), and later reported from an unspecified Mexican locality based on a specimen intercepted at Brownsville, Texas (Carvalho and Southwood 1955). The specimens listed below from Clay, Hidalgo, and Refugio counties represent the first authentic Texas records.

Type material examined. Holotype ♂ (00162202) (USNM) (macropterous): **UNITED STATES: Duval Co.:** Jacksonville, 30.33194°N, 81.65583°W, 23 Jul 1926, E. D. Ball. **Paratypes: UNITED STATES: Texas: Duval Co.:** Jacksonville, 30.33194°N, 81.65583°W, 23 Jul 1926, E. D. Ball, 1 ♂ (00161903) (USNM), 2 ♀♀ (00161912, 00161913), 1 nymph (00161910), 2 ♀♀ (00161914, 00161915) (USNM). **Texas: Presidio Co.:** Presidio, 29.56056°N, 104.37167°W, 28 Sep 1929, W.L. Owens, 1 ♂ (00167070) (CNC) (macropterous), 1 ♀ (00161911) (USNM) (brachypterous).

Other specimens examined. UNITED STATES: Florida: Texas: Cameron Co.: Brownsville, 25.90139°N, 97.49722°W, 28 Mar 1945, collector unknown, 1 ♀ (00161917) (USNM) (macropterous). Brownsville, Veteran's Bridge (Cargo Lot), 27 Jul 2011, S. Guzman, 1 ♂ (USNM). **Chambers Co.:** Anahuac, 29.77278°N, 94.6825°W, 08 Oct 1918, H. S. Barber, 1 ♂ (00161904) (USNM). **Clay Co.:** 6 mi NE of Bexar at Red River (at state line), 34.13611°N, 98.13055°W, 20 Sep 2009, G. F. and J. F. Hevel, 1 ♂ (00161909) (USNM) (macropterous). **Hidalgo Co.:** Hidalgo County, 26.1°N, 98.26278°W, 19 May 1930, J. C. Gaines, Paratype, 1 ♀ (00161916) (USNM). **Refugio Co.:** 6 mi. N. Bayside, Rt. 136, 20 Apr 1983, T. J. Henry and A. G. Wheeler, Jr, 4 ♂♂ (00161905 - 00161908) (USNM) (macropterous).

Tytthus chinensis (Stål)

http://species-id.net/wiki/Tytthus_chinensis

Figs 9, 10, 55–62, 121–124

Capsus chinensis Stål 1860: 258 (orig. descrip.); Atkinson 1890: 107 (cat.).

Cyrtorhinus chinensis: Reuter 1903: 22 (descrip.); Hsiao 1942: 255 (key).

Cyrtorhinus annulicollis Poppius 1915: 65 (orig. descrip.). Synonymized by Carvalho and Southwood 1955: 20.

Cyrtorhinus elongatus Poppius 1915: 65 (orig. descrip.). Synonymized by Carvalho and Southwood 1955: 20.

Cyrtorhinus riveri Cheesman 1927: 94 (orig. descrip.); Knight 1935: 204 (list); Usinger 1939: 270 (key, host), 1946: 79 (note), 1951: 4 (key). Synonymized by Carvalho and Southwood 1955: 20.

Tytthus chinensis: Carvalho and Southwood 1955: 19 (key, descrip.) Carvalho 1958: 157 (cat.); Tomokuni et al. 1993: 307 (note, photo); Schuh 1995: 248 (cat.); Cassis and Gross 1995: 204 (cat.); Kerzhner and Josifov 1999: 441 (cat.); Yasunaga et al. 2001: 182 (note, photo).

Tytthus koreanus Josifov and Kerzhner 1972: 171 (orig. descrip.); Kerzhner 1988: 840 (key); Schuh 1995: 249 (cat.); Kerzhner and Josifov 1999: 441 (cat.); Kwon et al. 2001: 184 (cat.). syn. n.

Diagnosis. This species is very similar to *T. parviceps* in general size and in sharing the dark base of each tibia, dark antennae with the apex and base of segment I pale, and short, erect, brushlike setae on antennal segment II. *Tytthus chinensis* almost always has a uniformly black pronotum (Figs 9, 10) or the pronotum with only weak indications of yellow around the calli, and the endosoma (Fig. 123) is C-shaped, whereas *T. parviceps* has the anterior one third to half of the pronotum around the calli almost always extensively pale yellow (Figs 32, 34) and the endosoma appears more distinctly S-shaped (Fig. 170). All known specimens of both species are macropterous.

Three other exclusively New World species, *T. entrerianus*, *T. femoralis*, and *T. mexicanus*, also have fuscous “knees,” a character that distinguishes them from all other species of the genus, except *T. chinensis* and *T. parviceps* as noted above and in the key. All three, however, lack the brushlike setae on antennal segment II and the apical one third to two thirds of the hind femora of these species are infuscated.

Description. *Male* (n = 15) (Fig. 9): Length to apex of hemelytron 2.18–2.60 mm, length to base of cuneus 1.65–1.88 mm, width across hemelytra 0.79–0.93 mm. *Head*: Length 0.27–0.29 mm, width across eyes 0.56–0.58 mm, interocular width 0.29–0.30 mm. *Labium*: Length 0.72–0.94 mm. *Antenna*: Segment I length 0.24–0.26 mm, II 0.78–0.82 mm, III 0.43–0.51 mm, IV 0.30–0.32 mm. *Pronotum*: Length 0.29–0.32 mm, basal width 0.69–0.80 mm.

Coloration: Uniformly fuscous to black, with a large, yellow, interocular spot touching inner margin of each eye, spots nearly contiguous in some individuals; eyes fuscous to dark reddish brown. *Labium*: Uniformly pale yellow, except of brown apical half of segment IV. *Antenna*: Segment I black, with base and apex narrowly pale yellow; segments II–IV uniformly fuscous to black. *Pronotum*: Usually uniformly black, anterior third around calli frequently weakly tinged with yellow, and less often entire anterior third yellow; posterior half uniformly fuscous to black. *Mesoscutum*: Uniformly yellowish brown to fuscous. *Scutellum*: Uniformly fuscous to black. *Hemelytron*: Uniformly translucent yellow to whitish. *Ostiolar evaporative area*: Yellowish, with central area of auricle invaded with fuscous, sometimes entirely fuscous. *Ventral surface*: Anterior half of proacetaula often yellow, propleura, pro- and mesosterna, and metapleura fuscous; abdomen

Figures 101–108. SEM photomicrographs of *Tytthus wheeleri*, male **101** dorsal habitus **102** lateral habitus **103** head and pronotum, dorsal aspect **104** head and pronotum, lateral aspect **105** head, anterior aspect **106** ostiolar evaporative area **107** genital capsule, caudal aspect **108** claw.

varying from largely yellowish, with only genital capsule fuscous or black to largely fuscous with only ventral area pale. *Legs*: Uniformly generally yellow; procoxae uniformly yellow, meso- and metacoxae dark brown at bases, yellow beyond; femora yellow, often tinged with orange; tibiae yellow, bases broadly fuscous; tarsi and claws yellowish.

Structure, texture, and vestiture: *Head*: Weakly shiny, impunctate; buccula slender, extending posteriorly, ending near level with hind margin of eye; thickly set with short to relatively long semierect setae, especially on frons. *Labium*: Extending to apices of meso- or bases of metacoxae; segment I extending beyond base of head to xyphus just before procoxae. *Antenna*: Segment I set with short, recumbent setae and two, long, subapical, bristlelike setae; segment II thickly set with short, recumbent setae, intermixed with row of longer, erect setae (Fig. 59) along ventral surface. *Pronotum*: Anterior angles rounded; lateral margins weakly concave, gradually widening to rounded posterior angles; posterior margin weakly sinuate. *Mesoscutum*: Weakly shiny, impunctate; set with a few scattered, semierect setae. *Scutellum*: Weakly shiny, impunctate; equilateral; set with a few scattered recumbent and semierect setae. *Hemelytron*: Macropterous, cuneus and membrane fully developed, extending posteriorly well beyond apex of abdomen; evenly set with relatively long, recumbent setae.

Male genitalia: *Left paramere* (Fig. 121): Mitt-shaped; right arm long, brown; left arm short, spinelike. *Right paramere* (Fig. 122): Oval. *Endosoma* (Fig. 123): C-shaped, apex blunt. *Phallosome* (Fig. 124): Relatively slender, strongly bent (C-shaped), apically acute.

Female (n = 15) (Fig. 10): Length to apex of hemelytron 2.50–2.78 mm, length to base of cuneus 1.86–2.00 mm, width across hemelytra 0.90–0.96 mm. *Head*: Length 0.29–0.30 mm, width across eyes 0.60–0.62 mm, interocular width 0.30–0.32 mm. *Labium*: Length 0.90–0.94 mm. *Antenna*: Segment I length 0.26–0.27 mm, II 0.45–0.46 mm, III 0.26–0.27 mm, IV 0.29–0.30 mm. *Pronotum*: Length 0.29–0.30 mm, basal width 0.80–0.85 mm.

Hosts. Usinger (1939) reported *T. chinensis* (as *Cyrtorhinus riveti*) feeding on the eggs of *Sogatia ochrias* (Kirkaldy) [Delphacidae] on *Sporobolus virginicus* (L.) Kunth [Poaceae] and *Nilaparvata lugens* (Stål) [Delphacidae] on rice (*Oryza* sp.) in Guam. He also recorded this species from Bermudagrass, *Cynodon dactylon* (L.) Pers., in Samoa, and *Tradescantia* sp. [Commelinaceae] in Tahiti.

Distribution. This species has been reported from central and southeastern China, Japan, Taiwan, and Australia, India, and the Indo-Pacific Region (Caroline Islands, Childers Island, Cook Islands, Fiji, Gilbert Island, Indonesia, Mariana Islands, Marshall Islands, New Caledonia, New Hebrides, Papua New Guinea, Philippine Islands, Pitcairn Island, Rapa Island, Ryukyu Islands, Samoa, Society Islands, Solomon Islands, South Korea, Swain Islands, and Tonga Islands) (Schuh 1984, 1995; Kerzhner and Josifov 1995; Cassis 1995). Based on specimens in the USNM, most or all records reported by Schuh (1984) from India and Sri Lanka should be applied to *T. parviceps*; Schuh's (1984) record from Hawaii is based on two specimens intercepted on international commerce at Honolulu (without origin indicated).

Based on specimens examined, I now also have records of this species from Cambodia, Guadalcanal, Guam, Saipan, and Tinian Island.

Discussion. Carvalho and Southwood (1955), after consulting with D. R. Malaise at the Swedish Museum of Natural History in Stockholm, reported that the type of *Capsus chinensis* Stål (1859) must be considered lost. Based on Stål's original description and study of other types, they concluded that *Cyrtorhinus elongatus* Poppius and *C. annulicornis* Poppius (both in Deutsches Entomologisches Institut) and *C. riveti* Cheesman (BMNH) are junior synonyms. They characterized *T. chinensis* as "the smallest species of *Tytthus* and is distinguished by its black pronotum and scutellum, the dark bases of the tibia and the small size." I have studied the type of *T. riveti* and agree that it follows the concept of *T. chinensis* outlined by Carvalho and Southwood (1955) and Carvalho (1956), including a uniformly dark pronotum.

In addition, Kerzhner and Josifov (1995) suggested that *T. koreanus* Josifov and Kerzhner (1972) could be a junior synonym of *T. chinensis*. Although I have not examined type material of *T. koreanus*, the description and figures presented in the original description indicate that this species is based on pale specimens having the calli or anterior third of the pronotum yellow to brownish yellow. Josifov and Kerzhner (1972) did not indicate if they observed specimens with entirely dark pronota. I also have studied a male and two females from South Korea, lent by Dr. Seunghwan Lee (SNU), that agree with the pale color form of *T. chinensis* having only the calli and mesoscutum tinged with dull brownish yellow. As a consequence, I consider *T. koreanus* and the material from Dr. Lee conspecific with that of *T. chinensis*.

Although most material of what I consider to be *T. chinensis* has a uniformly fuscous to black pronotum, varying degrees of yellow are present on the calli and anterior third of the pronotum on some specimens from eastern Asia, throughout the Indo-Pacific, and Australia, which may cause confusion with *T. parviceps* that also has yellow on the anterior area of the pronotum. Nevertheless, I consider all material from eastern Asia (including Korea and Japan), Indonesia, Malaysia, Australia, New Guinea, and the South Pacific Islands *T. chinensis* based on the dark pronotum in most specimens and C-shaped endosoma. However, because of the strong morphological similarity between *T. "chinensis"* and *T. "parviceps,"* an effort will be made to accumulate fresh material worldwide for conducting a phylogeographic analysis of species limits within this complex using mitochondrial cytochrome oxidase 1 (COI) sequence data in cooperation with colleagues S. Scheffer and M. Lewis (Systematic Entomology Laboratory, ARS, USDA, Beltsville, Maryland, USA).

For the time being, I am restricting the distribution of *T. parviceps* that has the anterior third of the pronotum broadly yellow (but certain specimens within populations can have a uniformly dark pronotum) to southern Asia (India, Srilanka, Pakistan, Vietnam, Thailand), the Middle East, Afrotropical and Neotropical regions, and subtropical United States. A few specimens from the Indo-Pacific (e.g., Guam), Australia, Cambodia, and other eastern Asian countries are externally indistinguishable from typical specimens of *T. parviceps* from Africa and the New World. As noted above, the endosoma of typical *T. chinensis* is C-shaped, whereas this very simple structure in African and New World specimens of *T. parviceps* is usually S-shaped. Until additional

collections can be made and additional DNA sequencing can be conducted on these populations, the strongly yellow phenotypes within populations of *T. chinensis* must be regarded as convergent color forms.

Type material examined. To ensure nomenclatural stability, I designate the following female as the lectotype of *Cyrtorhinus riveti*: Label 1 (circular label with orange ring) “Type”; label 2, “Tahiti: Nr. Papeete[,] Mar.-Apr.[,] Miss Cheesman”; label 3 (handwritten), “*Cyrtorhinus riveti* Cheesman”; label 4, “St. George Exp.[] BM 1925-235”; label 5 (00085518 (BMNH)).”

Tytthus columbiensis Carvalho

http://species-id.net/wiki/Tytthus_columbiensis

Fig. 11

Tytthus columbiensis Carvalho 1984: 202 (orig. descrip.); Schuh 1995: 248 (cat.)

Diagnosis. This distinct species is recognized by the overall shiny fuscous to black body, antennae, and femora, contrasting with the pale or white cuneus, basal area of corium and clavus, antennal segments III and IV, and tibiae.

It is similar to the Nearctic *T. montanus* in the overall dark brown to fuscous dorsum and femora and the basally pale corium, but differs in having most of the cuneus, antennal segments III and IV pale (segments I and II uniformly black) and most of the tibiae (except bases) pale or whitish, whereas in *T. montanus* the cuneus and antennal segment III and IV are uniformly black (segments I pale and II pale on basal third to half) and the tibiae are pale only on the distal halves.

Description. *Holotype male* (Fig. 11): Length to apex of hemelytron ca 3.40 mm (wing separated from body), length to base of cuneus 2.33 mm (wing separated from

Figures 109–116. Male genitalia **109–112** *T. alboornatus* **109** left paramere **110** right paramere **111** endosoma **112** phallosome **113–116** *T. amazonicus* **113** left paramere **114** right paramere **115** endosoma **116** phallosome.

body), width across hemelytra 1.12 mm. *Head*: Length 0.43 mm, width across eyes 0.64 mm, interocular width 0.32 mm. *Labium*: Length 1.12 mm. *Antenna*: Segment I length 0.32 mm, II 1.04 mm, III 0.64 mm, IV ca 0.51 mm (curled and in glue). *Pronotum*: Length 0.42 mm, basal width 0.82 mm.

Coloration: *Head*: Uniformly black, with a vague pale spot on interocular space adjacent to each eye; eyes dark reddish brown. *Labium*: Segments I, II, and apex of IV dark brown; segment III, apex of II, and basal two thirds of IV pale or whitish.

Antenna: Segments I and II fuscous to black; segment III and IV pale or whitish. *Pronotum*: Uniformly black. *Hemelytron*: Fuscous to black, with basal one fourth of corium and clavus and cuneus, except for apex, pale or white; membrane translucent brown. *Ostiole*: Fuscous to black. *Ventral surface*: Propleura black, ventral areas of thorax dark to reddish brown; abdomen dark reddish brown. *Legs*: Procoxae reddish brown, mesocoxa reddish brown with only apex pale, metacoxa uniformly pale to whitish; femora uniformly black; tibiae pale yellow to whitish, with only basal one fourth of each fuscous to black; tarsi and claws pale yellow to whitish.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, width subequal to length, shiny; buccula slender (less than half the width of labial segment I), tapering posteriorly; sparsely set with scattered, short, semierect, dark brown setae on vertex and frons and a few longer, erect setae along posterior margin. *Labium*: Extending to bases of mesocoxae; segment I extending only to base of head. *Pronotum*: Shiny, impunctate; anterior angles rounded, lateral margins weakly concave, posterior anterior angles strongly flared, posterior margin concave; sparsely set with scattered, short, erect and semierect, dark brown setae. *Mesoscutum*: Broadly exposed, impunctate, sparsely set with short, erect, dark brown setae. *Scutellum*: Equilateral, impunctate, sparsely set with short, erect, dark brown setae. *Hemelytron*: Macropterous, impunctate, basal width of cuneus about two thirds the length, membrane fully developed with two areoles; evenly set with short, semierect dark brown setae (pale setae on pale or white areas).

Male genitalia: The unique holotype was not dissected.

Female: Unknown.

Host. The holotype was taken on *Oryza* sp. (Poaceae).

Distribution. Described and known only from the holotype collected in Colombia.

Type material examined. **Holotype** ♂ (00162207) (USNM): **COLOMBIA: Valle del Cauca**: Palmira, 25 Oct. 1958, G. Bravo, Arroz, *Oryza* sp. (Poaceae).

Discussion. The left hemelytron of the holotype is missing, and the right one is glued to the point next to the specimen. Otherwise, the specimen is in reasonably good condition. Carvalho (1984) illustrated the holotype, apparently before the specimen was damaged. Figure 11 depicts the original condition, using Adobe Photoshop to reconstruct the position of both hemelytra.

Tytthus entrerianus Carvalho & Carpintero

http://species-id.net/wiki/Tytthus_entrerianus

Figs 12, 125–127

Tytthus entrerianus Carvalho and Carpintero 1986: 624 (orig. descrip.); Schuh 1995: 248 (cat.).

Diagnosis. This species is recognized by the dark brown head and antennal segments I and II, the pale brown pronotum with the anterior half darker brown or reddish brown,

Figures 117–124. Male genitalia **117–120** *T. balli* **117** left paramere **118** right paramere **119** endosoma **120** phallosome **121–124** *T. chinensis* **121** left paramere **122** right paramere **123** endosoma **124** phallosome.

the translucent, smoky-brown hemelytra, and the mostly pale legs with only the distal thirds of the femora fuscous. All known specimens of this species are macropterous.

This species keys to *T. femoralis* based on the pale tibiae with fuscous knee spots and the apically fuscous hind femora. *Tytthus entrerianus* can be distinguished from *T. femoralis* by the dark brown or fuscous antennal segment II and having only apical third of the hind femur infuscated.

Description. *Male* (n = 1, holotype in parentheses) (composite description based on Carvalho and Carpintero, 1986, and one USNM paratype) (Fig. 12): Length to apex of hemelytron 2.65 mm (3.00 mm), length to base of cuneus 1.80 mm (not given), width across hemelytra 0.74 mm (0.90 mm). *Head*: Length 0.40 mm (0.30 mm), width across eyes 0.54 mm (0.50 mm), interocular width 0.29 mm (0.30 mm).

Labium: Not visible, imbedded in glue (not given). *Antenna*: Segment I length 0.34 mm (0.30 mm), II 0.94 mm (1.00 mm), III 0.74 mm (0.70 mm), IV 0.56 mm (0.50 mm). *Pronotum*: Length 0.27 mm (0.20 mm), basal width 0.67 mm (0.70 mm).

Coloration: *Head*: Uniformly dark brown; pale spot near inner margin of eye absent. *Labium*: Not visible. *Antenna*: Segments I and II dark brown; segment III and IV brownish yellow. *Pronotum*: Anterior half dark brown; posterior half yellowish brown. *Mesoscutum*: Reddish brown. *Scutellum*: Reddish brown. *Hemelytron*: Brown, with basal one fourth and cuneus paler yellowish brown; membrane pale translucent brown. *Ostiolar evaporative area*: Brown. *Ventral surface*: Thorax and abdomen brown to reddish brown, genital capsule dark brown. *Legs*: Pale brownish yellow, apical third of each femur and bases of tibiae (knees) dark brown.

Structure, texture, and vestiture: Shiny, impunctate (buccula imbedded in glue); sparsely set with short, semierect setae. *Labium*: Not visible. *Antenna*: Segment I with a few scattered, short, recumbent setae and two long, erect, bristlelike setae at apex; segment II with relatively few, short, recumbent setae. *Pronotum*: Shiny, impunctate; anterior angles rounded; lateral margins straight, gradually widening to posterior angles; posterior margin weakly concave. *Mesoscutum*: Shiny, impunctate; set with only a few semierect setae. *Scutellum*: Shiny, impunctate; set with a few semierect setae. *Hemelytron*: Macropterous, impunctate, subparallel; length of cuneus two times length; membrane entire with two areoles; set with sparsely scattered, recumbent, brown setae.

Male genitalia (based on Carvalho and Carpintero's 1986, figures): *Left paramere* (Fig. 125): Mitt-shaped; right arm long, slender; left arm shorter, spinelike. *Right paramere* (Fig. 126): Oval. *Endosoma* (Fig. 127): C-shaped, with apparent secondary gonopore at middle. *Phallosome*: Not figured.

Female: None examined; described from 5 paratype ♀♀. Carvalho and Carpintero (1986) indicated that the general aspect and dimensions of females were similar to males.

Host. Unknown.

Distribution. Described and known only from Entre Rios Province, Argentina.

Type material examined. **Paratype:** ARGENTINA: **Entre Rios:** Concordia, 31.4°S, 58.033°W, 21 m, Apr 1939 [L. Carpintero], ♂ (00138710) (USNM).

Other specimen examined. ARGENTINA: **Entre Rios:** Concordia, 31.4°S, 58.033°W, Jan 1979, collector unknown, 1 ♂ (00138710) (USNM).

Tytthus femoralis Henry, sp. n.

urn:lsid:zoobank.org:act:B264F11F-69AD-4E03-8C44-70DE7060E461

http://species-id.net/wiki/Tytthus_femoralis

Figs 13, 14, 128–131

Diagnosis. This species is distinguished by the combination of a black head, pronotum, and scutellum; translucent hemelytra usually marked with dark brown through middle of the corium; the fuscous antennal segment I, with only the apex pale; the pale antennal segment II having a fuscous basal band; the fuscous hind femur contrasting

Figures 125–131. Male genitalia **125–128** *T. entrerianus* **125** left paramere **126** right paramere **127** endosoma **128–131** *T. femoralis* **128** left paramere **129** right paramere **130** endosoma **131** phallosome.

with the pale yellow pro- and mesofemora; and the pale tibiae with the bases or “knees” fuscous. All known specimens of this species are macropterous.

Tyttus femoralis keys to *T. entrerianus* based on the pale tibiae with knee spots and the apically infuscated hind femora. It can be distinguished from *T. entrerianus* by the pale antennal segment II and the more extensively infuscated hind femur.

Description. *Male* (n = 10, plus holotype in parentheses) (Fig. 13): Length to apex of hemelytron 2.56–3.42 mm (2.83 mm), length to base of cuneus 1.90–2.25 mm (2.08 mm), width across hemelytra 0.80–0.99 mm (0.88 mm). *Head:* Length 0.30–0.34 mm (0.35 mm), width across eyes 0.61–0.67 mm (0.63 mm), interocular width 0.27–0.29 mm (0.29 mm). *Labium:* Length 1.20–1.38 mm (1.28 mm). *Antenna:* Segment I length 0.38–0.50 mm (0.38 mm), II 0.94–1.21 mm (1.10 mm), III 0.58–0.72 mm (0.66 mm), IV 0.40–0.59 mm (0.58 mm). *Pronotum:* Length 0.34–0.38 mm (0.35 mm), basal width 0.75–0.90 mm (0.78 mm).

Coloration: *Head:* Uniformly fuscous to black, with a large, yellow, interocular spot near inner margin of each eye, spots nearly converging on some specimens; eyes fuscous to dark

reddish brown. *Labium*: Pale yellow, with apical half of segment IV brown. *Antenna*: Segment I fuscous to black, with apical one quarter pale or yellowish; segment II pale yellowish brown, with a distinct fuscous band at base and sometimes with apex infuscated; segments III and IV black. *Pronotum*: Uniformly black. *Mesoscutum*: Uniformly black. *Scutellum*: Uniformly black. *Hemelytron*: Translucent, with a dark brown cloud or patch on apical half of corium and inner apical half of clavus ranging from somewhat indistinct to a definite dark pattern (Figs 13, 14); membrane pale translucent brown. *Ostiole area*: Dark brown to fuscous, with a yellow patch on posterior edge. *Ventral surface*: Thorax and abdomen uniformly fuscous to black. *Legs*: Coxae pale yellow, with basal thirds to halves dark brown; pro- and meso femora pale yellow, metafemur dark brown to fuscous, with basal third and apex pale yellow; tibiae pale, each with a fuscous base or "knee"; tarsi, and claws pale yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate; buccula relatively broad, tapering posteriorly, ending near level with middle of eye; set with scattered, semierect setae. *Labium*: Extending to metacoxae or base of abdomen; segment I extending beyond base of head onto xyphus to bases of procoxae. *Antenna*: Segment I sparsely set with recumbent setae and two erect, subapical bristlelike setae; segment II set with only very short, recumbent setae. *Pronotum*: Shiny, impunctate; anterior angles rounded; lateral margins weakly concave, widening at posterior angles; posterior margin weakly sinuate; calli weakly swollen; set with relatively long, recumbent setae. *Mesoscutum*: Weakly shining, impunctate, broadly exposed; set with a few scattered semierect setae. *Scutellum*: Shiny, impunctate; equilateral; set with scattered erect and semierect setae. *Hemelytron*: Macropterous, with cuneus and membrane fully developed, extending well beyond apex of abdomen; evenly set with relatively long, recumbent setae.

Male genitalia: *Left paramere* (Fig. 128): Mitt-shaped; right arm long, broad, acute apically; left arm short, apically acute. *Right paramere* (Fig. 129): *Endosoma* (Fig. 130): S-shaped. *Phallosome* (Fig. 131): Slender, apically acute.

Female (n = 5) (Fig. 14): Length to apex of hemelytron 2.82–3.52 mm, length to base of cuneus 2.05–2.50 mm, width across hemelytra 1.00–1.14 mm. *Head*: Length 0.30–0.35 mm, width across eyes 0.62–0.69 mm, interocular width 0.30–0.32 mm. *Labium*: Length 1.12–1.50 mm. *Antenna*: Segment I length 0.32–0.50 mm, II 0.85–1.17 mm, III 0.53–0.75 mm, IV 0.54–0.59 mm.

Pronotum: Length 0.40–0.41 mm, basal width 0.91–0.99 mm.

Similar to males in general appearance and coloration, differing primarily in the overall broader form. The one color exception is that the ventral area of the abdomen in many females is pale yellow, whereas in males the abdomen is always uniformly fuscous to black.

Etymology. The specific epithet *A. "femoralis"* denotes the dark brown to fuscous hind femur in contrast to the uniformly pale pro- and mesofemora.

Hosts. Four specimens from San Carlos, Ecuador, with the label a "Host-Eggs of *Perkinsiella* spp." Three specimens intercepted on *Musa* sp. certainly represent incidental or sitting records.

Distribution. So far recorded from Bolivia, Brazil, Colombia, Costa Rica, Cuba, Ecuador, Guatemala, Honduras, Jamaica, Mexico, Panama, and Peru.

Type material. Holotype ♂ (00161890) (USNM): **ECUADOR: Manabi:** Bahia de Caraquez (35 kms SE), 10 May 1975, Ashley B. Gurney. **Paratypes: BOLIVIA: El Beni:** Capivara on Rio Itenez, approx. 20 km E. of Versailles, 22 Jul 1964, J. K. Bouseman, J. ***Tytthus fuscicornis* Henry, sp. n.**

urn:lsid:zoobank.org:act:208FF6B9-938A-4489-AE46-5E4AE9FD5624

http://species-id.net/wiki/Tytthus_fuscicornis

Figs 15, 16, 132–135

Diagnosis. This new species is distinguished by the small size, the uniformly dark brown head and pronotum, fuscous to black antennae with segment II thickened

and subequal to apical diameter of segment I, the pale or whitish hemelytra, and the brownish-yellow legs. The only known male (holotype) of this species is macropterous and the only known female is brachypterous with an abbreviated membrane.

It is superficially similar to several species, such as *T. mexicanus* and *T. panamensis*, based on the dark head, pronotum and scutellum and pale hemelytra. It is distinguished from these and all other species by the pale tibiae lacking knee spots, uniformly fuscous antennae, the thickened antennal segment II, pale femora, and relatively small size.

Description. *Holotype male* (Fig. 15): Length to apex of hemelytron 2.14 mm, length to base of cuneus 1.54 mm, width across hemelytra 0.69 mm. *Head*: Length 0.29 mm, width across eyes 0.51 mm, interocular width 0.29 mm. *Labium*: Length 0.69 mm. *Antenna*: Segment I length 0.22 mm, II 0.75 mm, III 0.43 mm, IV 0.29 mm. *Pronotum*: Length 0.27 mm, basal width 0.67 mm.

Coloration: *Head*: Uniformly dark brown, with a somewhat indistinct, small, yellow interocular spot near inner margin of eye; eyes dark brown to reddish brown, especially around margins. *Labium*: Uniformly brownish yellow, with only apex of segment IV dark brown or fuscous. *Antenna*: Uniformly fuscous to black. *Pronotum*: Uniformly dark brown. *Mesoscutum*: Dark brown. *Scutellum*: Dark brown. *Hemelytron*: Pale or whitish, evenly tinged with pale brown; membrane pale translucent brown. *Ostiolar evaporative area*: Pale brownish yellow. *Ventral surface*: Propleura dark brown; ventral areas of thorax and abdomen reddish brown, genital capsule darker brown to nearly black. *Legs*: Coxae pale to pale brownish yellow, with bases reddish brown; femora brownish yellow, tinged with orange or brownish orange; tibiae, tarsi, and claws pale brownish yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate; buccula slender, ending posteriorly about level with middle of eye; sparsely set with very short, recumbent and semierect, setae. *Labium*: Extending to apices of meso- or bases of metacoxae; segment I short, extending only slightly beyond base of head. *Antenna*: Segment I with only a few short, recumbent setae and two erect, subapical, bristlelike setae; segment I densely set with short, recumbent setae; segment II gradually thickened to apex, apical width equal to or greater than diameter of segment I. *Pronotum*: Shiny, impunctate; calli weakly swollen; anterior angles rounded; lateral margins nearly straight, gradually widening to posterior angles; basal margin weakly concave; sparsely set with only short, recumbent setae. *Mesoscutum*: Narrowly exposed; sparsely set with short, recumbent setae. *Scutellum*: Impunctate, weakly shiny; sparsely set with short, recumbent setae. *Hemelytron*: Entire, suparallel; length of cuneus about two times basal width; membrane with two areoles, extending well beyond apex of abdomen.

Male genitalia: *Left paramere* (Fig. 132): Mitt-shaped; right arm long, evenly slender, and rounded apically; left arm short, apically acute. *Right paramere* (Fig. 133): elongate oval. *Endosoma* (Fig. 134): C-shaped or weakly S-shaped. *Phallosome* (Fig. 135): Relatively slender, apically acute.

Brachypterous female (n = 1; somewhat teneral) (Fig. 16): Length to apex of hemelytron 1.57 mm, length to base of cuneus 1.36 mm, width across hemelytra 0.70 mm. *Head*: Length 0.27 mm, width across eyes 0.53 mm, interocular width 0.32 mm.

Figures 132–139. Male genitalia **132–135** *T. fuscicornis* **132** left paramere **133** right paramere **134** endosoma **135** phallosoma **136–139** *T. insperatus* **136** left paramere **137** right paramere **138** endosoma **139** phallosoma.

Labium: Length 0.64 mm. **Antenna:** Segment I length 0.19 mm, II 0.61 mm, III 0.40 mm, IV 0.27 mm. **Pronotum:** Length 0.27 mm, basal width 0.67 mm.

Similar to male in general coloration, but differing in the broader, more oval form, the slightly more slender antennal segment II (but with apex still nearly equal to apical diameter of segment I), and abbreviated hemelytron, with the length of the cuneus subequal to the basal width and the membrane shortened and extending only to the apex of the abdomen.

Host. Beaten by A. G. Wheeler from crowns of *Muhlenbergia rigens* (Benth) Hitchc. [Poaceae].

Distribution. Known only from New Mexico, USA.

Type material. **Holotype** ♂ (00161896) (USNM): **UNITED STATES: New Mexico: Grant Co.:** Little Walnut Road, Gila National Forest, North of Silver City, 12 May 2008, A. G. Wheeler, Jr. **Paratype:** Same data as for holotype, 1 ♀ (00161895) (USNM).

***Tytthus insperatus* (Knight)**

http://species-id.net/wiki/Tytthus_insperatus

Figs 17, 18, 136–139

Cyrtorhinus insperatus Knight 1925: 42 (orig. descrip.).

Tytthus insperatus: Carvalho and Southwood 1955: 31 (descrip., n. comb.); Carvalho 1958: 157 (cat.); Henry and Wheeler 1988: 458 (cat.); Schuh 1995: 248 (cat.).

Diagnosis. This species is distinguished by the black head and antennae, strongly infuscated or brown pronotum with the anterior collarlike margin narrowly whitish, the translucent smoky-brown hemelytra, and the orange-brown legs with a slender, dorsal and anterior red line on each femur, and a posterior red line on the metafemur. All known specimens of this species are fully macropterous.

Tytthus insperatus is similar to *T. balli* and *T. uniformis* in overall size, body shape, and general coloration. It differs from both species in having an imbrowned pronotum with a pale or white collar and distinct red lines on the femora.

Description. *Holotype male* (Fig. 17): Length to apex of hemelytron 2.98 mm, length to base of cuneus 2.06 mm, width across hemelytra 0.77 mm. *Head*: Length 0.45 mm, width across eyes 0.59 mm, interocular width 0.27 mm. *Labium*: Length 1.09 mm. *Antenna*: Segment I length 0.35 mm, II 1.44 mm, III 0.91 mm, IV 0.54 mm. *Pronotum*: Length 0.34 mm, basal width 0.70 mm.

Coloration: *Head*: Uniformly fuscous to nearly black, with only a small, indistinct pale, interocular spot near inner margin of each eye; eyes fuscous. *Labium*: Pale brownish yellow, apical half of segment IV darker brown. *Antenna*: Uniformly black. *Pronotum*: Dark brown, fading to paler orange brown posteriorly, narrow anterior collar white. *Mesoscutum*: Pale brownish orange. *Scutellum*: Pale brownish orange. *Hemelytron*: Uniformly pale translucent brown, with pale orange highlights; membrane clear or translucent. *Ostiolar evaporative area*: Pale brownish orange. *Ventral surface*: Thoracic area pale brownish orange; abdomen pale with green and orange highlights; genital capsule fuscous. *Legs*: Coxae pale brownish orange; femora pale brownish orange with a slender dorsal and anterior red stripe on pro- and mesofemora and a dorsal, anterior, and posterior red stripe on metafemur; tibiae, tarsi, and claws fuscous to black.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, width subequal to length; nearly glabrous with only a few scattered erect and semierect setae; buccula narrow, tapering posteriorly ending near level with middle of eye. *Labium*: Extending to mesocoxae; segment I not extending beyond base of head. *Antenna*: Segment I only slightly thicker than segment II, sparsely set with short, recumbent setae and two erect, subapical, bristlelike setae; segment II densely set with short, recumbent setae. *Pronotum*: Shiny, impunctate; calli weakly swollen; anterior angles angulate; lateral margins convex, flaring at posterior angles; posterior margin weakly concave; nearly glabrous, with only a few scattered, recumbent setae. *Mesoscutum*: Shiny, impunctate, with a few scattered, recumbent setae. *Scutellum*: Shiny, impunctate, with a few scattered, recum-

bent setae. *Hemelytron*: Macropterous, subparallel, cuneus and membrane fully developed, extending well beyond apex of abdomen; evenly set with short, recumbent setae.

Male genitalia: *Left paramere* (Fig. 136): Mitt-shaped; right arm, long, stout, bluntly rounded apically; left arm short, apically blunt. *Right paramere* (Fig. 137): Elongate oval. *Endosoma* (Fig. 138): Strongly S-shaped. *Phallosome* (Fig. 139): Slender, apically acute.

Female (n = 3) (Fig. 18): Length to apex of hemelytron 3.14–3.33 mm, length to base of cuneus 2.33–2.43 mm, width across hemelytra 0.96–1.06 mm. *Head*: Length 0.40–0.43 mm, width across eyes 0.61–0.66 mm, interocular width 0.32–0.34 mm. *Labium*: Length 1.12–1.15 mm. *Antenna*: Segment I length 0.32–0.34 mm, II 1.12–1.47 mm, III 0.96–1.01 mm, IV 0.53–0.54 mm. *Pronotum*: Length 0.34–0.37 mm, basal width 0.77–0.82 mm.

Similar to male in overall coloration and body form.

Host. Unknown. The Maricopa specimen below from “on cotton” almost certainly represents an incidental or sitting record.

Distribution. Described from Tucson (Pima County), Arizona, and later reported from Buckeye (Maricopa County), Arizona, and Calexico (Imperial County), California (Carvalho and Southwood 1955).

Type material examined. **Holotype** ♂ (00162203) (USNM): **UNITED STATES: Arizona: Pima Co.:** Tucson, 32.22167°N, 110.92583°W, 07 Jun 1924, A. A. Nichol., **Paratypes:** Same data as for holotype, 1 ♀ (allotype) (00161894) (USNM), 1 ♀ (00167071) (CNC).

Other specimens examined. **UNITED STATES: Arizona: Cochise Co.:** W Herford, Rio San Pedro, 4150', 22 July 1974, E. R. Hoebeke, 1 ♂ (CU). **Maricopa Co.:** Buckeye, 33.37028°N, 112.58306°W, 06 Jun 1935, H. G. Johnston, on cotton, 1 ♂ (00138719) (USNM).

Tytthus juturnaiba Carvalho & Wallerstein

http://species-id.net/wiki/Tytthus_juturnaiba

Figs 140–143

Tytthus juturnaiba Carvalho and Wallerstein 1978: 256 (orig. descrip.); Schuh 1995: 249 (cat.).

Diagnosis. Based on the original description and adult habitus illustration, this species can be distinguished by the overall dark color with the cuneus, embolium, and the narrow outer edge of the corium pale yellow, the medially fuscous membrane, the dark antennal segment I with only the apex pale, and the pale antennal segment II with the apex fuscous. This combination of characters places *T. juturnaiba* near the North American *T. vagus*, but differs in having an apparent pale yellow antennal segment II, with only the apex black, and uniformly pale yellow legs, whereas *T. vagus* has a uniformly black antennal segment II, and the hind femur is fuscous on the apical two thirds.

I have, however, studied a photograph of the holotype of *T. juturnaiba* stored in the PBI Heteroptera Species Database (http://research.amnh.org/pbi/heteropteraspeciespage/popupimage.php?imagenam=AMNH_PBI_00174988.jpg) that appears to indicate that antennal segment I actually is pale at the base and apex (not just pale at the apex) and segment II is uniformly dark (not yellow, with the apex fuscous). Based on this photograph, which contradicts the antennal characters described in the original description, *T. juturnaiba* almost certainly is conspecific with *T. neotropicalis* and would run to this species in my key. Nevertheless, I refrain from making a formal synonymy until I can examine the holotype (which was unavailable at the time of this study) deposited in the Museu Nacional, Rio de Janeiro, Brazil.

Description. *Holotype male* (based Carvalho and Wallerstein 1978): Length to apex of hemelytron 2.90 mm, width across hemelytra 0.90 mm. *Head*: Length 0.20 mm, width across eyes 0.60 mm, interocular width 0.28 mm. *Antenna*: Segment I length 0.30 mm, II 0.80 mm, III 0.50 mm, IV missing. *Pronotum*: Length 0.40 mm, basal width 0.80 mm. *Cuneus*: Length 0.40 mm, basal width 0.28 mm.

Coloration (based on Carvalho and Wallerstein 1978): General coloration black, outer margin of exocorium, embolium, and cuneus pale yellow; middle of membrane fuscous; antenna pale yellow, segment I (except extreme apex) and apex of segment II black. Undersurface black. Legs pale yellow.

Structure, texture, and vestiture (based on Carvalho and Wallerstein 1978): Information not given.

Male genitalia (based on Carvalho and Wallerstein 1978): *Left paramere* (Fig. 140): Mitt-shaped; right arm longest; left arm shorter, spinelike. *Right paramere* (Fig. 141): Elongate oval. *Endosoma* (Fig. 142): Strongly C-shaped, bent at middle. *Phallosome* (Fig. 143): Broad, apically acute.

Female (based on Carvalho and Wallerstein 1978): Length to apex of hemelytron 3.20 mm, width across hemelytra 1.00 mm. *Head*: Length 0.20 mm, width across eyes 0.50 mm, interocular width 0.28 mm. *Antenna*: Segment I length 0.20 mm, II 0.80 mm, III and IV missing. *Pronotum*: Length 0.40 mm, basal width 0.90 mm. *Cuneus*: Length 0.44 mm, basal width 0.28 mm.

Host. Unknown.

Distribution. Described and known only from the holotype and allotype taken at Logoa Juturnaiba, Araruama, Estado do Rio de Janeiro, Brazil, Nov. 1976 (Carvalho and Wallerstein 1978).

Specimens examined. None.

Tytthus mexicanus Henry, sp. n.

urn:lsid:zoobank.org:act:12D9E8C9-F915-463E-A1F4-22F8D2E97CB0

http://species-id.net/wiki/Tytthus_mexicanus

Figs 19, 20, 144–147

Diagnosis. This species is distinguished by the black antennae, except for the pale apex of segment I; the black pronotum; the brown mesoscutum and scutellum; the smoky

Figures 140–147. Male genitalia **140–143** *T. juturnaiba* **140** left paramere **141** right paramere **142** endosoma **143** phallosome **144–147** *T. mexicanus* **144** left paramere **145** right paramere **146** endosoma **147** phallosome.

brown to dirty white hemelytra; and the pale yellowish legs, with distinct black spines and knee spots at the bases of the tibiae.

Tytthus mexicanus is most similar to *T. femoralis* and *T. entrerianus* based on the pale tibiae with knee spots and antennal segment II lacking erect, bristlelike setae. It can be distinguished from both species by the uniformly pale hind femora and dark brown to fuscous antennal segment II.

Description. *Male* (n = 4; plus holotype in parentheses) (Fig. 19): Length to apex of hemelytron 2.75–2.58 mm (2.55 mm), length to base of cuneus 2.90–2.05 mm, width across hemelytra 0.88–0.93 mm (0.86 mm). *Head*: Length 0.32–0.34 mm (0.30 mm), width across eyes 0.59–0.61 mm (0.59 mm), interocular width 0.27–0.29 mm (0.27 mm). *Labium*: Length 1.12–1.14 mm (1.12 mm). *Antenna*: Segment I length

0.30–0.34 mm (0.32 mm), II 0.91–1.07 (1.02 mm), III 0.54–0.64 mm (0.58 mm), IV 0.51–0.64 mm (missing). *Pronotum*: Length 0.34–0.35 mm (0.32 mm), basal width 0.78–0.82 mm (0.77 mm).

Coloration: *Head*: Uniformly fuscous to black, with a large, distinct, pale yellow, interocular spot near inner margin of each eye, spots nearly contiguous in some specimens; eyes reddish brown, often fading to silver with a reddish tinge. *Labium*: Uniformly pale yellow; apex of segment IV dark brown to fuscous. *Antenna*: Segment I fuscous to black, with apical one fourth yellow (length of yellow area equal to diameter of segment) and narrowed basal one fourth shiny; segment II dark brown to black (basal area darker on “paler” dark brown segments); segments III and IV dark brown to fuscous. *Pronotum*: Uniformly shiny fuscous, weakly swollen calli sometimes very slightly paler brown. *Mesoscutum*: Dark brown to fuscous, lateral angles pale yellow on some specimens. *Scutellum*: Dark brown to fuscous, slightly paler apically. *Hemelytron*: Pale translucent smoky brown to dirty white; veins brown and often narrow inner margin of clavus brown. *Ostiolar evaporative area*: Dark brown to fuscous, often invaded with pale areas posteriorly. *Ventral surface*: Thorax uniformly dark brown to fuscous; abdomen dark brown to fuscous laterally, pale ventrally, genital capsule black. *Legs*: Coxae pale brownish yellow, with bases brown; femora uniformly pale yellow to whitish; tibia pale yellow to whitish with spines and bases, or knees, dark brown to fuscous; tarsi and claws pale yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, wider than long; buccula relatively narrow, ending posteriorly near level with middle of eye; sparsely set with long, erect and suberect, pale brown to brown setae. *Labium*: Extending to bases of hind coxae or just onto abdominal segment II; segment I extending to bases of fore coxae. *Antenna*: Segment I with short, recumbent setae and two long, black, bristlelike setae near apex before pale area; segment II thickly set with short, recumbent pale brown setae much shorter than diameter of segment. *Pronotum*: Shiny, impunctate; calli weakly swollen but distinct; anterior rounded; lateral margins concave, strongly flaring at posterior angles; posterior margin weakly sinuate; set with short, erect to semierect setae. *Mesoscutum*: Shiny, impunctate, broadly exposed; with numerous semierect and recumbent, pale brown setae. *Scutellum*: Shiny, impunctate; thickly set with semierect and recumbent pale brown setae. *Hemelytron*: Macropterous, subparallel when paired, with fully developed cuneus and membrane, extending well beyond apex of abdomen; evenly scattered with short, recumbent, pale brown setae.

Male genitalia: (Fig. 144): Mitt-shaped; right arm longest, stout, slightly constricted basally, weakly pointed apically; left arm short, apically acute. *Right paramere* (Fig. 145): Elongate oval, strongly rounded apically. *Endosoma* (Fig. 146): C-shaped, nearly S-shaped with apical quarter curving slightly upward. *Phallosome* (Fig. 147): moderately stout, apically acute.

Female: (n = 2) (Fig. 20): Length to apex of hemelytron 2.88–2.93 mm, length to base of cuneus 2.10–2.23 mm, width across hemelytra 0.99–1.04 mm. *Head*: Length 0.32–0.37 mm, width across eyes 0.61–0.62 mm, interocular width 0.29–0.30 mm. *Labium*: Length 1.20–1.22 mm. *Antenna*: Segment I length 0.29–0.30 mm, II 0.88–

0.91 mm, III 0.61–0.64 mm, IV 0.61–0.62 mm. *Pronotum*: Length 0.35–0.37 mm, basal width 0.86–0.88 mm.

Similar to male in general color and pubescence, differing primarily in the slightly broader form.

Etymology. Named for the country in which it was collected, Mexico.

Host. Unknown.

Distribution. Known only from Baja California Sur, Nayarit, and Sinaloa, Mexico.

Type material. **Holotype** ♂ (00166142) (USNM): **MEXICO: Sinaloa: Culiacan Co.:** Camino Real Tres Rios, 3 km N Mex. 15 at toll bridge gate, 08 Aug 1981, S. Tytthus montanus Carvalho & Southwood

http://species-id.net/wiki/Tytthus_montanus

Figs 21–23, 148–151

Tytthus montanus Carvalho and Southwood 1955: 32 (orig. descrip.); Carvalho 1958: 157 (cat.); Henry and Wheeler 1988: 458 (cat.); Schuh 1995: 249 (cat.).

Diagnosis. This species is distinguished by the overall dark brown to nearly black coloration, with the basal thirds of the corium and clavus white, the pale yellow antennal segment I and black segment II, the dark brown metafemur, and pale yellow tibiae. It is known from only two macropterous males (Fig. 21), one macropterous female (Fig. 22), and numerous brachypterous females (Fig. 23).

Tytthus montanus is similar to *T. wheeleri* in having mostly dark brown hemelytra with only the base pale or white but is distinguished from that species by the larger size (2.70 mm vs. less than 2.00 mm in *T. wheeleri*), pale yellow antennal segment I, red-streaked pro- and mesofemora, and dark brown metafemur (versus entirely pale yellow legs in *T. wheeleri*). It is also similar to *T. alboornatus* but is distinguished by the distally dark hemelytron (versus distally white or pale cuneus or pale area across posterior margin of hemelytra in brachypters).

Description. *Macropterous male* (n=1; holotype in parentheses) (Fig. 21): Length to apex of hemelytron 2.83 mm (2.75 mm), length to base of cuneus 1.98 mm (1.75 mm), width across hemelytra mm. *Head*: Length 0.38 mm (0.37 mm), width across eyes 0.64 mm (0.64 mm), interocular width 0.34 mm (0.32 mm). *Labium*: Length

0.98 mm (0.93 mm). *Antenna*: Segment I length 0.27 mm (0.30 mm), II 0.93 mm (0.93 mm), III 0.56 mm (missing), IV mm (missing). *Pronotum*: Length 0.45 mm (0.43 mm), basal width 0.72 mm (0.74 mm).

Coloration: *Head*: Dark reddish brown (holotype) to black; pale yellow interocular spot near inner margin of eye indistinct; eyes dark brown to nearly black. *Labium*: Mostly pale yellow, with segment I and apex of segment IV dark brown. *Antenna*: Segment I pale yellow, narrowly fuscous at base; segments II mostly fuscous to black, with only base pale yellow; segments III–IV nearly black (segments II–IV yellowish brown in holotype). *Pronotum*: Uniformly dark brown (holotype) to black. *Mesoscutum*: Uniformly dark brown (holotype) to black. *Scutellum*: Uniformly dark brown (holotype) to black. *Hemelytron*: Largely dark brown (holotype) to black, with only basal third of corium and clavus white; membrane translucent brown to smoky black. *Ostiolar evaporative area*: Dark reddish brown (holotype) to black. *Ventral surface*: Uniformly dark reddish brown (holotype) to black. *Legs*: Coxa pale yellow, reddish brown or black at bases; pro- and mesofemora pale yellow, lightly tinged with pale orange to more reddish brown with bases pale (holotype), metafemur dark reddish brown (holotype) to dark brown, with basal one third and apex pale yellow; pro- and mesotibiae pale yellow to more reddish brown with bases pale, metatibia yellow (holotype) to dark brown; tarsi and claws pale yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, width subequal to length; buccula very narrow, tapering posteriorly, ending at level before middle of eye. *Labium*: Extending to bases of mesocoxae; segment I not extending to base of head. *Antenna*: Segment I with only very short, fine, recumbent setae, with two erect, subapical, bristlelike setae; segment II thickly set with short, recumbent setae, intermixed with a few more erect, short setae on distal half. *Pronotum*: Shiny, with a glaucous sheen over weakly defined calli, impunctate; anterior angles rounded, lateral margins concave, strongly flaring at posterior angles; posterior margin weakly sinuate; sparsely set with short, fine, recumbent setae. *Mesoscutum*: Shiny, impunctate, with a few scattered, recumbent setae. *Scutellum*: Shiny, impunctate, with a few short, fine, recumbent setae. *Hemelytron*: Macropterous, cuneus and membrane fully developed, extending well beyond apex of abdomen; evenly set with scattered, short, fine, recumbent setae.

Male genitalia: *Left paramere* (Fig. 148): Mitt-shaped; right arm longest, stout, distally blunt; left arm short, blunt. *Right paramere* (Fig. 149): Oval. *Endosoma* (Fig. 150): C-shaped to weakly S-shaped. *Phallosome* (Fig. 151): Slender, apically acute.

Macropterous female (n = 1) (Fig. 22): Length to apex of hemelytron 2.65 mm, length to base of cuneus 1.87 mm, width across hemelytra 0.94 mm. *Head*: Length 0.37 mm, width across eyes mm, interocular width 0.32 mm. *Labium*: Length 0.91 mm. *Antenna*: Segment I length 0.22 mm, II 0.59 mm, III 0.40 mm, IV 0.40 mm. *Pronotum*: Length 0.42 mm, basal width 0.72 mm.

Very similar to the two macropterous males in overall shape and structure, differing in the significantly shorter antennal segments and in having all femora and the basal halves of the tibiae dark brown to fuscous.

Figures 148–155. Male genitalia **148–151** *T. montanus* **148** left paramere **149** right paramere **150** endosoma **151** phallosome **152–155** *T. mundulus* **152** left paramere **153** right paramere **154** endosoma **155** phallosome.

Brachypterous female (n = 5) (Fig. 23): Length to apex of hemelytron 1.85–2.20 mm, length to base of cuneus 1.53–1.75 mm, width across hemelytra 0.77–0.86 mm. *Head*: Length 0.38–0.42 mm, width across eyes 0.61–0.62 mm, interocular width 0.32–0.34 mm. *Labium*: Length 0.88–0.91 mm. *Antenna*: Segment I length 0.22–0.24 mm, II 0.64–0.78 mm, III 0.35–0.42 mm, IV 0.34–0.35 mm. *Pronotum*: Length 0.37–0.40 mm, basal width 0.56–0.58 mm. Similar to macropters in overall color pattern, but like the macropterous female, differing from males in the shorter antennal segment and darkened femora.

Similar in color to the macropterous males and the one macropterous female, but differing especially in the nearly quadrate pronotum that has only weakly flared posterior margins and the brachypterous hemelytron with a greatly shortened cuneus (frac-

ture still visible on most specimens) and a much abbreviated membrane lacking any trace of areoles (Fig. 23).

Host. No specific host. Specimens from Arizona were swept from a dry grass and flower meadow in eastern Arizona; the one male from Utah was beaten from the bases of bunch grasses.

Distribution. Described and previously known only from Montana. Arizona and Utah represent new state records.

Discussion. Although I have considered the series of 18 females collected in Arizona by Leonard Kelton (CNC) conspecific with the holotype male and one other male taken in northern Utah, I note that all femora of this southern population are uniformly dark except at the bases, whereas the Montana and Utah males have pale front and middle femora and only the hind femora dark. In addition, the actual measurements of the antennal segments are considerably smaller in these females than males, a variation not observed in other species.

Type material examined. **Holotype** ♂ (macropterous) (00162198) (USNM): **UNITED STATES: Montana: Granite Co.:** Drummond, July 10, 1935, Oman.

Other specimens examined. **UNITED STATES: Arizona: Apache Co.:** Big Lake, Apache National Forest, 33.88667°N, 109.41667°W, 2774 m, 12 Aug 1967 - 14 Aug 1967, L. A. Kelton, 18 ♀♀ (00112047 - 00112061, 00112063, 00161925 - 00161926) (CNC). **Utah: Cache Co.:** 0.4 mi off Rt 89 along Franklin Basin Rd, 41.93555°N, 111.57222°W, 2004 m, 17 Jul 2001 - 18 Jul 2001, T. J. Henry and A. G. Wheeler, Jr., 1 ♂ (00161897) (USNM).

Tytthus mundulus (Breddin)

http://species-id.net/wiki/Tytthus_mundulus

Figs 24, 25, 152–155

Periscopus mundulus Breddin 1896: 106 (orig. descrip.).

Cyrtorhinus mundulus: Reuter 1902: 178 (descrip.); Kirkaldy 1908: 378 (list); Poppius 1914: 168 (list); Muir 1920: 125 (notes); Williams 1931: 103 (notes); Swezey 1936: 79 (notes, history); Usinger 1939: 271 (key, host); Zimmerman 1948: 206 (note); Usinger 1951: 4 (descrip.).

Tytthus mundulus: Carvalho and Southwood 1955: 26 (key, descrip.); Carvalho 1958: 158 (cat.); Nguyen et al. 1984: 265 (note); Henry and Wheeler 1988: 458 (cat.); Schuh 1995: 249 (cat.); Cassis and Gross 1995: 204 (cat., hosts); Kerzhner and Josifov 1999: 441 (cat.); Wheeler 2000: 665 (hosts, biol., distr.), 2001: 278 (hosts, biol., distr.); Yasunaga et al. 2001: 182 (note, photo).

Diagnosis. *Tytthus mundulus* is distinguished by the fuscous to black head, pronotum, and scutellum; the translucent hemelytra with the clavus, most of the corium, and membrane tinged with brown; and the yellow legs and antennal segment I (apex sometimes narrowly infuscated), with contrasting fuscous to black antennal segments II–IV.

Antennal segment II has short erect setae along the entire dorsal and ventral surface (most evident ventrally), similar to those found on in *T. chinensis* and *T. parviceps*; *T. mundulus*, however, lacks the fuscous knee spots found in these two species. All known specimens of this species are macropterous.

Description. *Male* (n = 5) (Fig. 24): Length to apex of hemelytron 3.07–3.26 mm, length to base of cuneus 2.21–2.30 mm, width across hemelytra 0.93–1.01 mm. *Head*: Length 0.34–0.35 mm, width across eyes 0.70–0.72 mm, interocular width 0.34–0.35 mm. *Labium*: Length 1.04–1.15 mm. *Antenna*: Segment I length 0.38–0.40 mm, II 1.23–1.26 mm, III 0.66–0.67 mm, IV 0.54–0.56 mm. *Pronotum*: Length 0.38–0.40 mm, basal width 0.83–0.86 mm.

Coloration: *Head*: Uniformly black, with an indistinct, pale yellow, interocular spot near inner margin of each eye; eyes dark reddish brown. *Labium*: Pale yellow, with only apical half of segment IV brown. *Antenna*: Segment I pale yellow, sometimes tinged with pale brownish orange, apex sometimes narrowly dark brown; segments II–IV dark brown to fuscous. *Pronotum*: Uniformly shiny, black. *Mesoscutum*: Shiny black. *Scutellum*: Shiny black. *Hemelytron*: Clavus, inner two thirds of corium and most of membrane tinged with brown to dark brown, leaving only outer margin of corium clear. *Ostiolar evaporative area*: Dark brown to fuscous. *Ventral surface*: Uniformly dark brown to fuscous. *Legs*: Coxae yellow, with bases dark brown to fuscous; femora, tibiae, tarsi, and claws uniformly yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, with a glaucous patch along inner margin of each eye; wider than long; buccula relatively broad, ending near level with posterior margin of eye; sparsely set with short, recumbent setae, more so on glaucous patches, and with a few longer, erect setae along posterior margin. *Labium*: Extending to bases of mesocoxae; segment I extending beyond base of head to anterior edge of prosternum. *Antennae*: Segment I sparsely set with short, fine, recumbent setae and two erect, subapical, bristlelike setae; segment II thickly set dorsally and ventrally with short, erect and semierect, somewhat bristlelike setae, forming a “bottlebrush” appearance (similar to *T. chinensis*). *Pronotum*: Shiny, impunctate; calli weakly swollen; anterior angles rounded; lateral margins weakly concave, moderately flaring at posterior angles; posterior margin sinuate; thickly set with semierect and recumbent setae. *Mesoscutum*: Shiny, impunctate, broadly exposed; with semierect and recumbent setae. *Scutellum*: Shiny, impunctate, equilateral; thickly set with semierect and recumbent setae. *Hemelytron*: Macropterous, subparallel when paired, with fully developed cuneus and membrane, extending well beyond apex of abdomen.

Male genitalia: *Left paramere* (Fig. 152): Mitt-shaped; right arm longest, gradually tapering to a point; left arm short, apically acute. *Right paramere* (Fig. 153): Elongate oval. *Endosoma* (Fig. 154): Strongly C-shaped. *Phallosome* (Fig. 155): Relatively slender, apically acute.

Female (n = 5) (Fig. 25): Length to apex of hemelytron 3.07–3.64 mm, length to base of cuneus 2.27–2.66 mm, width across hemelytra 1.04–1.22 mm. *Head*: Length 0.35–0.37 mm, width across eyes 0.74–0.77 mm, interocular width 0.35–0.37 mm. *Labium*: Length 1.06–1.22 mm. *Antenna*: Segment I length 0.34–0.38 mm, II 0.98–

1.10 mm, III 0.58–0.59 mm, IV 0.50–0.58 mm. *Pronotum*: Length 0.40–0.43 mm, basal width 0.91–1.01 mm.

Hosts. This species is an egg predator of the sugarcane delphacid, *Perkinsiella sacharicida* Kirkaldy (Zimmerman 1948, Wheeler 2001). It has also been taken on corn and taro in Hawaii.

Distribution. This Indo-Pacific species has been reported from Fiji, Hawaii, New Caledonia, Papua New Guinea, the Philippine Islands, and Queensland, Australia (Schuh 1984). It has been successfully introduced into Hawaii to control the sugarcane delphacid (Zimmerman 1948, Carvalho and Southwood 1955), representing one of the best examples of successful classical biological control (Wheeler 2001). It was released in Florida, according to Nguyen et al. (1984), but apparently it has not become established (Wheeler 2001). It was also introduced into South Africa to control a tropiduchid, *Numicia viridis* Muir, on sugarcane but without success (Carnegie and Harris 1969). See Wheeler (2001) for additional information about this beneficial species.

Specimens examined. AUSTRALIA: Queensland: North Queensland Co.: Halifax Apr. 1920, F. Muir, 1 ♀ (BMNH). Upper Mulgrave River, 8 miles from Goldsborough Road, 09 May 1967, D. H. ***Tytthus neotropicalis* (Carvalho)**

http://species-id.net/wiki/Tytthus_neotropicalis

Figs 26, 27, 63–70, 156–159

Cyrtorhinus costae: Carvalho 1945: 316 (misident., habitus, parameres).

Cyrtorhinus neotropicalis Carvalho 1954: 425 (orig. descrip.).

Tytthus neotropicalis: Carvalho and Southwood 1955: 25 (n. comb.); Carvalho 1958: 158 (cat.); Carvalho and Rosas 1965: 210 (list); Maldonado 1969: 88 (descrip., Figs); Carvalho and Afonso 1977: 9 (list); Schuh 1995: 249 (cat.); Hernández and Henry 2010: 123 (diag., hosts).

Diagnosis. This species is readily distinguished from all other species of *Tytthus* by the dark brown to fuscous head, pronotum, and scutellum; pale translucent hemelytra; pale yellow legs; and especially the pale first antennal segment having a broad, dark band through the middle. No other species has a broad band on antennal segment I with the base and apex pale. Males and females of this species are always macropterous.

As noted in the diagnosis of *T. juturnaiba*, a photograph of the holotype stored in the PBI Heteroptera Species Database contradicts the color of antennal segments I and II described in the original description. If my interpretation of the banded antennal segment I in the photograph is correct, the two species probably are conspecific. A final decision, however, must await examination of the holotype of *T. juturnaiba*.

Description. *Male* (n = 10) (26, 63, 64): Length to apex of hemelytron 2.40–2.60 mm, length to base of cuneus 1.68–1.80 mm, width across hemelytra 0.82–0.83 mm. *Head*: Length 0.27–0.29 mm, width across eyes 0.54–0.59 mm, interocular width 0.27–0.29 mm. *Labium*: Length 0.94–1.07 mm. *Antenna*: Segment I length 0.24–0.29 mm, II 0.75–0.96 mm, III 0.37–0.51 mm, IV 0.32–0.34 mm. *Pronotum*: Length 0.32–0.34 mm, basal width 0.74–0.77 mm.

Coloration: *Head* (Figs 65–67: Uniformly black, with an indistinct, pale yellow, interocular spot near inner margin of each eye; eyes reddish brown. *Labium*: Pale yellow, with apical half of segment IV brown. *Antenna*: Segment I pale or whitish on apical and basal fourth, with a broad, uniformly dark brown to fuscous band through middle and a very narrow dark brown ring at base; segments II–IV uniformly dark brown to fuscous. *Pronotum*: Uniformly dark brown to fuscous. *Mesoscutum*: Uniformly dark brown to fuscous. *Scutellum*: Uniformly dark brown to fuscous. *Hemelytron*: Translucent, highlighted or tinged with pale brown on clavus and inner half of corium, inner half of clavus along claval commissure accented with darker brown; translucent dusky brown. *Ostiole*: Dark reddish brown. *Ventral surface*: Thorax

and abdomen uniformly dark reddish brown to fuscous. *Legs*: Coxae pale yellow, with bases reddish brown; femora pale yellowish, with metafemur sometimes accented with pale orange; tibiae, tarsi, and claws (Fig. 70) pale yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, wider than long; buccula narrow, tapering posteriorly, ending near hind margin of eye; set with scattered, relatively long, semierect setae. *Labium*: Extending just beyond metacoxae to base of abdomen; segment I extending past base of head to middle of xyphus before procoxae. *Antenna*: Segment I with short, relatively sparse, recumbent setae and two or three erect, subapical, bristlelike setae; segment II evenly set with short, recumbent setae. *Pronotum*: Shiny, impunctate; calli weakly swollen, entire area covered with a glaucous sheen; anterior angles rounded; lateral margins concave, strongly flaring at posterior angles; posterior margin weakly sinuate; evenly set with recumbent and semierect setae, especially on disc. *Mesoscutum*: Broadly exposed; set with scattered semierect setae. *Scutellum*: Impunctate, equilateral; set with scattered, relatively long, semierect setae. *Hemelytron*: Macropterous, cuneus and membrane fully developed, extending well beyond apex of abdomen; evenly set with recumbent setae.

Male genitalia (Fig. 69): *Left paramere* (Fig. 156): Mitt-shaped; right arm long and broad, tapering to a point apically; left arm shorter, pointed. *Right paramere* (Fig. 157): Elongate oval. *Endosoma* (Fig. 158): Strongly C-shaped. *Phallosome* (Fig. 159): Relatively slender, apically acute.

Female (n = 10) (Fig. 27): Length to apex of hemelytron 2.66–3.01 mm, length to base of cuneus 2.02–2.18 mm, width across hemelytra 0.96–1.04 mm. *Head*: Length 0.29–0.32 mm, width across eyes 0.56–0.61 mm, interocular width 0.27–0.32 mm. *Labium*: Length 1.06–1.17 mm. *Antenna*: Segment I length 0.26–0.27 mm, II 0.70–0.86 mm, III 0.45–0.54 mm, IV 0.43–0.45 mm. *Pronotum*: Length 0.32–0.35 mm, basal width 0.80–0.86 mm.

Similar to males in overall appearance, differing primarily in the slightly broader body form.

Hosts. No specific host known. Associated with grass savannas and marshes and pine-oak sand scrub.

Distribution. This species was described from Brazil (Carvalho 1954) and later reported from Ecuador, Peru, Puerto Rico, Surinam (Schuh 1995), and Cuba (Hernández and Henry 2010). New country records are Argentina, Belize, Bolivia, Brazil, Guyana, Haiti, Mexico (Veracruz), Nicaragua, Panama, Paraguay, the United States (Florida), and Venezuela.

Specimens examined. **ARGENTINA: Misiones:** Parque Nacional de Iguazú, 25.61666°S, 54.33333°W, Dec 1975, collector unknown, 1 ♀ (00095357) (AMNH). **BELIZE: Toledo:** Punta Gorda, 16.1°N, 88.8°W, Mar 1931, J.J. ***Tytthus pallidus* Henry, sp. n.**

urn:lsid:zoobank.org:act:E2C46E49-A43D-4C0B-9742-FBAFF41F3C2D

http://species-id.net/wiki/Tytthus_pallidus

Figs 28, 29, 160–163

Diagnosis. This species is recognized by the combination of the dark brown head, pronotum, and scutellum; the pale antennal segment I, with only the base fuscous, the brown antennal segment II; and the uniformly pale yellow legs. All known specimens are macropterous.

Tytthus pallidus keys out with *T. piceus* based on the pale antennal segment I and the pale hemelytra with smoky-brown shading. It can be distinguished from *T. piceus* by the broader head, the longer antennal segment I that is longer than the interocular width, and the less prominent calli lacking a glaucous sheen.

Description. *Holotype male* (Fig. 28): Length to apex of hemelytron 2.88 mm, length to base of cuneus 2.21 mm, width across hemelytra 0.88 mm. *Head*: Length 0.35 mm, width across eyes 0.61 mm, interocular width 0.29 mm. *Labium*: Length 1.31 mm. *Antenna*: Segment I length 0.35 mm, II 1.22 mm, III and IV missing. *Pronotum*: Length 0.35 mm, basal width 0.75 mm.

Coloration: *Head*: Uniformly dark brown; pale interocular spot found in all other species apparently absent; fuscous to dark reddish brown. *Labium*: Pale brownish yellow. *Antenna*: Segment I uniformly pale yellow, with a dark brown or fuscous ring at base; segments II–IV dark brown. *Pronotum*: Uniformly dark brown. *Mesoscutum*: Uniformly dark brown. *Scutellum*: Uniformly dark brown. *Hemelyton*: Uniformly pale translucent brown. *Ostiole evaporative area*: Dark brown to fuscous. *Ventral surface*: Thorax dark brown to dark reddish brown; abdomen dark reddish brown on segment II, III, and genital capsule, slightly paler in between. *Legs*: Coxa pale yellow, reddish brown at bases; femora, tibiae, tarsi, and claws uniformly pale yellow.

Structure, texture, and vestiture: *Antenna*: Segment I set with a few, scattered, recumbent setae and two erect, subapical, bristlelike setae. *Labium*: Extending beyond metacoxae to abdominal segment II or III. *Pronotum*: Shiny, impunctate; anterior angles rounded; lateral margins weakly concave, flaring at posterior angles; posterior margin distinctly sinuate; calli weakly swollen; set with relatively long, semierect setae. *Mesoscutum*: Impunctate, broadly exposed; with a few scattered semierect setae. *Scutellum*: Weakly shining, impunctate; equilateral; set with scattered, semierect setae. *Hemelytra*: Macropterous, cuneus and membrane fully developed, extending well beyond apex of abdomen.

Male genitalia: *Left paramere* (Fig. 160): Mitt-shaped; right arm long, broad, apically blunt; left arm short, apically acute. *Right paramere* (Fig. 161): Round. *Endosoma*: Teneral and damaged; not drawn. *Phallosome* (Fig. 162): slender, apically acute.

Female (n = 4) (Fig. 29): Length to apex of hemelytron 2.69–3.33 mm, length to base of cuneus 2.05–2.40 mm, width across hemelytra 0.82–1.02 mm. *Head*: Length 0.32–0.38 mm, width across eyes 0.56–0.64 mm, interocular width 0.29–0.30 mm. *Labium*: Length 1.12–1.44 mm. *Antenna*: Segment I length 0.26–0.34 mm, II 0.85–1.23 mm, III 0.61–0.78 mm, IV 0.51–0.56 mm. *Pronotum*: Length 0.29–0.37 mm, basal width 0.69–0.85 mm.

Etymology. The specific epithet “pallidus” refers to the characteristic pale yellow first antennal segment.

Host. Unknown.

Distribution. Known from Brazil and Panama.

Type material. **Holotype** ♂ (00162199) (USNM): **PANAMA: Darien:** [Pinogana District], El Real, 19 Mar. 1953, F. S. Blanton, 1 ♂ (USNM). El Real, 08 Aug 1952, F. S. ***Tytthus panamensis* Carvalho & Southwood**

http://species-id.net/wiki/Tytthus_panamensis

Figs 30, 31

Tytthus panamensis Carvalho and Southwood 1955: 32 (orig. descrip.); Carvalho 1958: 158 (cat.); Carvalho and Afonso 1977: 9 (list); Carvalho and Froeschner 1987: 218 (list, type info.); Schuh 1995: 249 (cat.); Froeschner 1999: 133 (list, note).

Diagnosis. *Tytthus panamensis* is a small species distinguished by the combination of the fuscous head, pronotum, and scutellum; the fuscous antennal segment I, with only the apex pale; the pale yellowish brown antennal segment II; and the uniformly pale legs. All known specimens are macropterous.

It is most similar to *T. pallidus*, sp. n. in overall size and color, including the reduced or apparent lack of an interocular spot on the head and the uniformly pale legs. It differs in having a dark brown antennal segment I, with only the apex pale, and a pale brown antennal segment II, whereas *T. pallidus* has a pale antennal segment I, with only a narrow dark ring at the base, and segment II is dark brown. *Tytthus panamensis* keys near *T. vagus* based on the dark antennal segment I with only the apex pale, but can be distinguished by the uniformly pale yellowish brown antennal segment II and hind femur.

Description. *Male* (n = 1, plus holotype in parentheses) (Fig. 30): Length to apex of hemelytron 2.21 mm (2.37 mm), length to base of cuneus 1.57 mm (1.63 mm), width across hemelytra 2.21 mm (2.37 mm). *Head:* Length 0.26 mm (0.29 mm), width across eyes 0.48 mm (0.51 mm), interocular width 0.24 mm (0.26 mm). *Labium:* Length 0.85 mm (0.93 mm). *Antenna:* Segment I length 0.30 mm (0.35 mm), II 0.88 mm (0.99 mm), III missing (0.56 mm), IV missing (missing). *Pronotum:* Length 0.22 mm (0.22 mm), basal width 0.58 mm (0.66 mm).

Coloration: *Head:* Uniformly dark brown, pale interocular spot found in all other species (except *T. pallidus*) apparently absent; eyes dark brown to fuscous. *Labium:* Uniformly pale yellow. *Antenna:* Segment I dark brown, narrowly pale at apex; segment II pale yellowish brown; segments III and IV brown. *Pronotum:* Uniformly dark brown. *Mesoscutum:* Uniformly dark brown. *Scutellum:* Uniformly dark brown. *Hemelytron:* Uniformly pale translucent brown. *Ostiole area:* Reddish brown. *Ventral surface:* Thorax and abdomen uniformly dark reddish brown. *Legs:* Procoxae

pale yellow; meso- and metacoxae pale yellow, with bases reddish brown; femora, tibiae, tarsi, and claws uniformly pale yellow.

Structure, texture, and vestiture: *Head:* Shiny, impunctate; buccula slender, tapering posteriorly, ending near level with middle of eye. *Labium:* Extending to apices of meso- or bases of metacoxae; segment I extending beyond base of head to anterior edge of xyphus before procoxae. *Antenna:* Segment I with relatively sparse, short, recumbent setae and two, long, subapical, bristlelike setae; segment II thickly set with short, recumbent setae, intermixed with a few more scattered, semierect setae. *Pronotum:* Shiny, impunctate; anterior angles weakly rounded; lateral margins straight, gradually widening to posterior angles; basal margin weakly sinuate; set with scattered recumbent and semierect setae. *Mesoscutum:* Shiny, impunctate, broadly exposed; set with a few short, semierect setae. *Scutellum:* Shiny, impunctate, equilateral; set with a few scattered, short, recumbent and semierect setae. *Hemelytron:* Macropterous, cuneus and membrane fully developed, extending posteriorly well beyond apex of abdomen; evenly set with relatively long, recumbent setae.

Male genitalia: Not examined. See note below.

Female (n = 1) (Fig. 31): Length to apex of hemelytron 2.91 mm, length to base of cuneus 1.98 mm, width across hemelytra 0.80 mm. *Head:* Length 0.34 mm, width across eyes 0.59 mm, interocular width 0.29 mm. *Labium:* Length 1.20 mm. *Antenna:* Missing. *Pronotum:* Length 0.27 mm, basal width 0.74 mm.

Similar to male in overall appearance, differing primarily in the broader body form.

Host. Unknown.

Distribution. Described and known only from Panama.

Discussion. The one male paratype previously had been dissected and the genitalia apparently were placed in a glass genitalia vial sealed with a cork stopper. Since that dissection, the cork has dried and crumbled and the genitalia are missing from the vial. I now have placed the glass vial inside a polyethylene vial, sealed it with a neoprene stopper, and reattached it to the specimen pin.

Type material examined. **Holotype** ♂ (00162200) (USNM): **PANAMA: Canal Zone:** Corozal, 8.98844°N, 79.5719°W, 14 Apr 1912, A. Busck, at light. **Paratypes:** Same data as for holotype, 1 ♂ (00161395) (USNM), 1 ♀ (00161394) (USNM).

Other specimens examined. **PANAMA: Canal Zone:** Fort Gulick, 9.31667°N, 79.86667°W, 21 Aug 1952, F. S. Blanton, 1 ♀ (00162201) (USNM). **Darien:** Garachine, 8.06472°N, 78.36277°W, 17 Feb 1953, F. S. Blanton, 1 ♀ (00161396) (USNM).

Diagnosis. This widespread circumtropical species is best distinguished by the pale yellow anterior area of the pronotum on almost all specimens, a characteristic found only in some specimens of *T. chinensis* and certain color forms of *T. pygmaeus*. It is also recognized by the combination of the black head, with large, yellow interocular spots; black antennal segment I, with the apex and base of segment I narrowly pale, yellowish-brown to brown segment II with the base black (but often uniformly fuscous or black); black scutellum, pale translucent hemelytra; and uniformly pale yellow legs, with a fuscous knee spot on each tibia. *Tytthus parviceps* is readily distinguished from *T. pygmaeus* by the knee spots at the bases of the tibiae. From *T. chinensis* it is distinguished by the usually extensively yellow anterior third to one half of the pronotum and the more strongly C-shaped (Fig. 165) endosoma. Only macropterous individuals of this species are known.

Description. *Male* (n = 10) (Fig. 32): Length to apex of hemelytron 2.11–2.46 mm, length to base of cuneus 1.50–1.70 mm, width across hemelytra 0.74–0.82 mm. *Head*: Length 0.26–0.27 mm, width across eyes 0.53–0.56 mm, interocular width 0.27–0.29 mm. *Labium*: Length 0.82–0.86 mm. *Antenna*: Segment I length 0.24–0.26 mm, II 0.72–0.80 mm, III 0.42–0.48 mm, IV 0.37–0.40 mm. *Pronotum*: Length 0.27–0.30 mm, basal width 0.67–0.74 mm.

Coloration: *Head*: Uniformly fuscous to black, with a large, yellow, interocular spot touching inner margin of each eye, spots nearly contiguous in some individuals; eyes fuscous to dark reddish brown. *Labium*: Uniformly pale yellow, except brown apical half of segment IV. *Antenna*: Segment I black, with the apex pale yellow; segment II yellowish brown to brown, with base black but sometimes uniformly black; segments III–IV uniformly fuscous to black. *Pronotum*: Anterior half typically broadly yellow from margin to margin, sometimes yellow area reduced so lateral margins and area between calli become invaded with fuscous, to the extreme with yellow greatly reduced

or absent; posterior half uniformly fuscous to black. *Mesoscutum*: Uniformly yellowish brown to fuscous. *Scutellum*: Uniformly fuscous to black. *Hemelytron*: Uniformly translucent yellow. *Ostiole evaporative area*: Uniformly yellow to yellow with central area of auricle invaded by fuscous. *Ventral surface*: Anterior half of proacetabula yellow, propleura, pro- and mesosterna black; metapleura yellowish, invaded by fuscous; abdomen largely yellowish, with only genital capsule fuscous or black. *Legs*: Uniformly yellow, with only bases of tibiae fuscous.

Structure, texture, and vestiture: *Head*: Weakly shiny, impunctate; buccula slender, extending posteriorly, ending near level with hind margin of eye; thickly set with short to relatively long semierect setae, especially on frons. *Labium*: Extending to apices of meso- or bases of metacoxae; segment I extending beyond base of head to xyphus just before procoxae. *Antenna*: Segment I set with short, recumbent setae and two, long, subapical, bristlelike setae; segment II thickly set with short, recumbent setae, intermixed with row of longer, erect setae (similar to *T. chinensis*) along ventral surface. *Pronotum*: Anterior angles rounded; lateral margins weakly concave, gradually widening to rounded posterior angles; posterior margin weakly sinuate. *Mesoscutum*: Weakly shiny, impunctate; set with a few scattered, semierect setae. *Scutellum*: Weakly shiny, impunctate; equilateral; set with a few scattered recumbent and semierect setae. *Hemelytron*: Macropterous, cuneus and membrane fully developed, extending posteriorly well beyond apex of abdomen; evenly set with relatively long, recumbent setae.

Male genitalia: *Left paramere* (Fig. 163): Mitt-shaped; right arm long, broad, almost triangular, bluntly pointed apically; left arm relatively long, apically pointed. *Right paramere* (Fig. 164): Oval. *Endosoma* (Fig. 165): Strongly C-shaped, blunt apically. *Phallosome* (Fig. 166): Slender, apically acute.

Female (n = 10) (Figs 33, 34): Length to apex of hemelytron 2.40–3.04 mm, length to base of cuneus 1.79–2.21 mm, width across hemelytra 1.02–1.09 mm. *Head*: Length 0.29–0.30 mm, width across eyes 0.59–0.64 mm, interocular width 0.30–0.32 mm. *Labium*: Length 0.88–1.04 mm. *Antenna*: Segment I length 0.26–0.29 mm, II 0.69–0.86 mm, III 0.43–0.56 mm, IV 0.43–0.50 mm. *Pronotum*: Length 0.34–0.38 mm, basal width 0.86–0.98 mm.

Similar to male, differing primarily in the larger size and broader body form.

Hosts. In the New World, *T. parviceps* has been associated with the delphacid *Saccarosydne saccharivora* (Westwood) (Carvalho and Southwood 1955) and the sugarcane delphacid, *Perkinsiella saccharicida* Kirkaldy (Sosa 1985), on sugarcane in Florida and Ecuador. It also has been taken on *Spartina alterniflora* Loisel [Poaceae] in North Carolina (Wheeler and Henry 1992). In the Old World, it is known to prey on eggs of the brown plant hopper, *Nilaparvata lugens* (Stål), in India and sugarcane delphacid in Australia (Bull 1981).

Distribution. In the New World, this widespread circumtropical and subtropical species is known from Central and South America (see specimen data below), the West Indies, Bermuda, and Florida and North Carolina in the United States (Henry and Hilburn 1990, Wheeler and Henry 1992). In the Old World, it has been reported from southern Europe, the Middle East, Africa, eastern (Far-Eastern Russia, Korea)

Figures 163–170. Male genitalia **163–166** *T. parviceps* **163** left paramere **164** right paramere **165** endosoma **166** phallosome **167–170** *T. piceus* **167** left paramere **168** right paramere **169** endosoma **170** phallosome.

and southeastern Asia, Australia, India, and islands in the Indian, Pacific, and southern Atlantic oceans (Wheeler and Henry 1992, Kerzhner and Josifov 1999). Cassis and Gross (1995) omitted this species from the Australian list, suggesting that reports in the literature should be referred to the similar-appearing *T. chinensis*.

Discussion. *Tytthus parviceps*, described from Egypt, is similar to *T. chinensis* in nearly all external characters, except for the strongly pale yellow anterior area around the calli of the pronotum, which may cause considerable confusion between these species when individuals of *T. parviceps* with greatly reduced yellow markings or an entirely dark pronotum are encountered, or when specimens of *T. chinensis* with more extensive yellow markings are found. Dissection of representative males of *T. parviceps* from different regions (list localities) shows that the endosoma is consistently S-shaped, whereas specimens of *T. chinensis* from (list localities) have a C-shaped endosoma.

China (1924) synonymized *Cylloceps pellicia* Uhler with *Cyrtorhinus parviceps* after examining the “type-specimen” deposited in the Natural History Museum (BMNH). I have examined the female syntype of *Cyrtorhinus parviceps* from Egypt and a female

syntype of *Cylloceps pellicia* from St. Vincent in the Natural History Museum, as well as a male syntype of *C. pellicia* from Cuba (labeled in Uhler's hand) in the USNM collection, and agree that Uhler's species is a junior synonym of *T. parviceps* as now defined.

Also, Josifov and Kerzhner (1972), in describing *T. koreanus*, initially indicated that it was similar to *T. parviceps* (Reuter) based on the extensive pale areas on the pronotum. However, they also added that the new species might be conspecific with *T. chinensis* described from Hong Kong, which according to the original description (Stål 1860) and to Reuter (1903) is a larger species (3.00 mm) than *T. parviceps*. Unfortunately, the type of *T. chinensis* is lost and the current concept of this species was established by Carvalho and Southwood (1955) and Carvalho (1956) as smaller, with the pronotum entirely black. I have examined a large amount of material from Australia and the Indo-Pacific Region that contains a few individuals among mostly black specimens exhibiting a yellow pronotal color not too unlike that described by Josifov and Kerzhner (1972) for *T. koreanus*. In addition, I have studied three specimens from Korea that also have more yellow on the anterior area of the pronotum but less than for typical specimens of *T. parviceps*. As a consequence, I am treating *T. koreanus* as a junior synonym of *T. chinensis* (which see) until additional studies can show otherwise.

Type material examined. To ensure nomenclatural stability, I am selecting the following syntypes as lectotypes:

Cyrtorhinus parviceps ♀ (BMNH): label 1 (circular label with orange ring) "Type"; label 2, "Le Cairo, V. 86, E. Antian, Schweinfor"; label 3 "Cyrtorhinus parviceps Reut. type; label 4 (here added, red printed label), "**LECTOTYPE:** ♀, *Cyrtorhinus parviceps* Uhler, by T. J. Henry"; label 4 "00085519 (BMNH).

Cylloceps pellicia: ♂ (USNM): label 1, "Cuba"; label 2 (handwritten), "152"; label 3, "PR Uhler Collection"; label 4 (handwritten), "Cylloceps pellicia Cuba: Uhler"; label 5 (handwritten, except "Det. Uhler"), "Cylloceps pellicia Uhler Cuba [printed] Det Uhler"; label 6 (name handwritten; remainder printed), "Tytthus parviceps (Rt.) det JCMCarvalho"; label 7 (here added, printed red label), "**LECTOTYPE:** ♂, *Cylloceps pellicia* Uhler, by T. J. Henry." A female from "St. Vincent, May, H. H. Smith" in the BMNH with 00085520 (BMNH) is here designated as a paralectotype.

Other specimens examined. **ANTIGUA AND BARBUDA: Antigua:** Galleon Beach, 03 Aug 1992, H.V. & R.M. Baranowski, 2 ♀♀ (00161495, 00161496) (USNM). **BAHAMAS: Andros Island:** Fresh Creek, 24.7°N, 77.76666°W, 23 Apr 1953, E.B. Hayden, 1 ♂ (00165901) (plus 10 ♂♂, 3 ♀♀) (AMNH). Mangrove Cay, 24.28333°N, 77.66666°W, 26 Apr 1953, E.B. Hayden, 12 ♂♂ (00165889 - 00165900), 6 ♀♀ (00165861 - 00165866) (AMNH). **Bimini:** South Bimini Island, 25.70623°N, 79.28204°W, 6 m, Jun 1951, Cazier and C. & P. Vaurie, 1 ♀ (00165913) (AMNH). **Exuma Cays:** Staniard Cay, 24.18333°N, 76.41666°W, 13 Jan 1953, E. B. Hayden & L. Giovannoli, 9 ♂♂ (00165876 - 00165884), 7 ♀♀ (00165867 - 00165873) (AMNH). **Nassau: New Providence Co.:** New Providence Island, 03 Jan 1953, E.B. Hayden, 1 ♀ (00165874) (AMNH). **San Salvador Island:** nr. Cockburn Town, 24.0333°N, 74.5167°W, 18 Mar 1953, L. Giovannoli & G.B. Rabb, 4 ♂♂ (00165885 - 00165888), 1 ♂ (00165875) (AMNH). **BARBADOS:** H.

H. Smith, 1 ♂ (BMNH). **BELIZE: Belize:** Big Falls Ranch, 23 Dec 1975, R. Akers, *Oryza sativa* (Poaceae), 1 ♂ (00161546) (USNM). **BERMUDA: Devonshire Parish:** Devonshire Marsh, 13 Jan 1988, T. J. Henry, 1 ♂ (00161503) (USNM); 14 Jul 1988 - 22 Jul 1988, M.R. Wilson & D.J. Hilburn, 1 ♂ (00161502) (USNM). **Paget Parish:** Paget Marsh, 23 Jul 1971, N. L. H. Krauss, 1 ♂ (00161505) (USNM); 13 Jan 1988, T. J. Henry, 1 ♀ (00161504) (USNM); 14 Jul 1988 - 22 Jul 1998, M.R. Wilson & D.J. Hilburn, 15 ♂♂ (00161468 - 00161482), 3 ♀♀ (00161483 - 00161485) (USNM) (an additional 10 ♂♂, 5 ♀♀ in BMNH). **BRAZIL: Para: Santarem Co.:** Taperinha, 11 Jun 1927 - 20 Jun 1927, Zerny, 1 ♀ (00161614) (USNM). **BURKINA FASO: Kadiogo:** Upper Volta, Ouagadougou, 03 Nov 1973 - 05 Nov 1973, R. Linnavuori, 1 ♂ (00166054), 3 ♀♀ (00166055 - 00166057) (AMNH). **CAMEROON:** Locality unknown, 1983, Irct A. Renou, 3 ♂♂ (00161707 - 00161709), 4 ♀♀ (00161705 - 00161706, 00161767 - 00161768), 2 nymphs (00161710, 00161711) (USNM). **CAYMAN ISLANDS: Grand Cayman:** Grand Cayman, 05 Aug 1988, P. Fitzgerald, 1 nymph (00161587) (USNM). **CHAD:** Farcha, 20 May 1973 - 22 May 1973, R. Linnavuori, 1 ♀ (00166052) (AMNH). **CHILE: Vicuna:** El Pangué, Nov 1961, L.E. Peña, 2 ♂♂ (00161464, 00161465), 1 ♀ (00161466) (USNM). **COSTA RICA: Guanacaste:** 10 mi NW of Liberia, 10.723°N, 85.344°W, 25 Jul 1965, Paul J. Spangler, 1 ♀ (00161586) (USNM). **CUBA: Cienfuegos:** La Jiquima, 29 Jul 1956, J. M. Osorio, 2 ♂♂ (00161519, 00161520), 6 ♀♀ (00161521 - 00161526) (USNM). **La Habana:** Alamar-Cojimar, 10 m, 04 May 1966 - 05 May 1966, Jar. Prokop, 1 ♂ (00161463) (USNM). **Habana-Marianao,** 15 m, 15 Jun 1966 - 20 Jul 1966, F. Gregor, 1 ♂ (00161462) (USNM). **Pinar del Rio:** La Jiquima, 27 Jul 1956, J. Acuna, 5 ♂♂ (00161729 - 00161730, 00161539, 00161729 - 00161730), 6 ♀♀ (00161540 - 00161544, 00161728) (USNM). **DEMOCRATIC REPUBLIC OF THE CONGO: Haut-Katanga:** Lubumbashi, 10 Apr 1971 - 11 Apr 1971, R. Linnavuori, 1 ♂ (00166024) (AMNH); 25 Apr 1971 - 26 Apr 1971, R. Linnavuori, 1 ♂ (00166023) (AMNH). **Nord-Kivu:** Lac Edouard, 15 Jan 1936, Dr. H. Damas, 1 ♂ (00161766) (USNM). **DOMINICAN REPUBLIC: La Altagracia:** Nisibon, 03 May 1978, Woodruff & Fairchild, 1 ♀ (00161584) (USNM). **Nisibon,** Finca Papagayo, 46 m, 04 Apr 2000 - 07 Apr 2000, T. J. Henry and R. E. Woodruff, 5 ♂♂ (00161486 - 00161490), 3 ♀♀ (00161491 - 00161493) (USNM). **Pendernales:** Cabo Rojo, Alcoa Headquarters, 13 Jun 1988, R. E. Woodruff, 1 ♀ (00161583), 1 ♀ (00161582) (USNM). **Puerto Plata:** Rio Camu, 19 km NE of Jarabacoa, 12 Jun 1969, Flint & Gomez, 1 ♀ (00161591) (USNM). **San Juan:** Locality unknown, 18.88°N, 71.27°W, 19 Oct 1967, collector unknown, 1 ♀ (00161550) (USNM). **San Pedro de Macoris:** Santo Domingo, 8 mi up Macoris river, 16 Jul 1917, Harold Morrison, 3 ♂♂ (00161536 - 00161538) (USNM). **ECUADOR: El Oro:** Victoria-Arenillas, 150 m, 18 Aug 1977 - 19 Aug 1977, L. Pena G., 1 ♂ (00161580) (USNM). **Guayas:** Ingenio San Carlos, 29 Nov 1995, Walter Gordillo, 1 ♂ (00161547), 2 ♀♀ (00161548, 00161549) (USNM). **Imbabura:** Otavalo, 01 Jan 1970, R. Levi-Castillo, 1 ♂ (00161531), 2 ♀♀ (00161530, 00161610) (USNM). **Pichincha:** Ingenio San Car-

los, 07 May 1982, Robert Morey, 1 ♂ (00161721), 1 ♀ (00161722) (USNM). **EGYPT: 6th of October Governorate:** W. Desert, Bahariya Oasis, 12 May 1995, Dr. Ullrich, 1 ♂ (00161648) (USNM); 30 Apr 1996, Dr. Ullrich, 2 ♂♂ (00161651, 00161652), 2 ♀♀ (00161649, 00161650) (USNM). **Aswan:** Aswan, 24.0875°N, 32.8989°E, 25 Dec 1993, Dr. Ullrich, 2 ♂♂ (00161572, 00161573), 1 ♀ (00161571) (USNM). **Cairo Governorate:** 25 km SW of Cairo, Wadi Digla, 23 Jan 1998, Dr. Ullrich, 1 ♂ (00161575), 1 ♀ (00161576) (USNM). Cairo, Digla, Road to Wadi Digla, 29.95861°N, 31.32041°E, 01 Feb 1998, Dr. Ullrich, 4 ♂♂ (00161657 - 00161660), 3 ♀♀ (00161661 - 00161663) (USNM); 11 Feb 1998, Dr. Ullrich, 1 ♂ (00161577), 1 ♀ (00161616) (USNM). Dahshur, ca. 23 km S. Cairo, 29.79908°N, 31.24625°E, 29 May 1996, Dr. Ullrich, 12 ♂♂ (00161617 - 00161624, 00161632 - 00161633, 00161645 - 00161646), 17 ♀♀ (00161625 - 00161630, 00161634 - 00161644), 1 nymph (00161631) (USNM). Isopropa picea Osborn and Drake 1915: 533 (orig. descrip.); Carvalho 1952: 72 (as type); Carvalho 1958(2): 201 (cat.); Cassis 1984: 165 (subfam. note); Schuh 1995: 498 (cat.).

Tytthus hondurensis Carvalho 1984: 203 (orig. descrip.); Schuh 1995: 248 (cat.). **syn. n.**

Diagnosis. This species, known from macropterous males and females (Figs 35, 36) and brachypterous females (Fig. 37), is distinguished by the bulbous black head, the black pronotum and scutellum having a distinct glaucous sheen, the raised finely punctate pronotal calli, the pale translucent-brown hemelytra, and the pale yellow to white first antennal segment with a narrow black ring at the base.

Tytthus piceus keys out with *T. pallidus*, n. sp but can be distinguished by the bulbous head, especially in males, the shorter antennal segment I that is only subequal to the interocular width, and the distinct calli that are covered in a glaucous sheen.

Description. *Male* (n = 10; holotype in parentheses) (Figs 35, 71, 72): Length to apex of hemelytron 2.35–2.50 mm (2.70 mm), length to base of cuneus 1.70–1.75 mm (1.89 mm), width across hemelytra 0.62–0.66 mm (wings folded). *Head*: Length 0.34–0.37 mm (0.35 mm), width across eyes 0.51–0.54 mm (0.50 mm), interocular width 0.24–0.26 mm (0.26 mm). *Labium*: Length 1.07–1.14 mm (imbedded in glue). *Antenna*: Segment I, length 0.26–0.27 mm (antennae missing); II, 0.98–1.02 mm; III, 0.50–0.56 mm; IV, 0.40–0.50 mm. *Pronotum*: Length 0.32–0.34 mm (0.32 mm), basal width 0.59–0.61 mm (0.59 mm).

Coloration: *Head* (Figs 73–75): Shiny black; eyes black. *Labium*: Segment I fuscous to black, apex paler yellowish brown, tinged with red or reddish brown in some specimens; segments II–IV pale yellowish brown, apex of segment IV fuscous. *Antenna*: Segment I pale yellowish brown to white, with a narrow black ring at base; segments II–IV uniformly black. *Pronotum, mesoscutum, and scutellum*: Shiny black, with a distinct glaucous sheen. *Hemelytron*: Uniformly smoky brown, slightly darker brown on clavus. *Ostiolar evaporative area* (Fig. 76): Dark reddish brown to fuscous. *Ventral surface*: Thorax dark brown or fuscous; abdomen in males dark brown, sometimes paler ventrally, genital capsule fuscous to black; abdomen in females yellowish green to pale brown, with broad lateral margins and ovipositor fuscous to black. *Legs*: Uniformly yellowish brown, inner face of pro- and mesofemora and outer face of metafemur usually with a narrow reddish line; claw (Fig. 78).

Structure, texture, and vestiture: *Head*: Impunctate, round or bulbous in both sexes, slightly wider than long; with scattered, long, erect setae on frons and vertex and a few short, erect setae on eyes. *Labium*: Extending to abdominal segment II or III. *Pronotum*: Trapeziform, narrowest anteriorly, lateral margins weakly concave, flaring to humeral angles; impunctate, except for a few scattered punctures on distinctly swollen calli. *Mesoscutum*: Broadly exposed. *Scutellum*: Equilateral, weakly convex, rising just

above level of hemelytra. *Hemelytron*: Translucent, subparallel; in macropterous males and females (Figs 35, 36) cuneus longer than wide at base, membrane fully developed, extending well beyond apex of abdomen; in brachypterous females (Fig. 37) lateral margins slightly more rounded than macropters, cuneus reduced to about as wide as long, membrane greatly reduced, extending only to the sixth or seventh abdominal tergite, exposing apex of abdomen.

Male genitalia: *Left paramere* (Fig. 167): Mitt-shaped; right arm long, wide, apically blunt; left arm shorter, apically pointed. *Right paramere* (Fig. 168): Elongate oval. *Endosoma* (Fig. 169): Strongly C-shaped, apically blunt. *Phallosome* (Fig. 170): Relatively slender, apically acute.

Macropterous female (n = 10) (Fig. 36): Length to apex of hemelytron 2.60–2.85 mm, length to base of cuneus 1.85–2.05 mm, width across hemelytra 0.70–0.83 mm. *Head*: Length 0.35–0.40 mm, width across eyes 0.54–0.58 mm, interocular width 0.27–0.29 mm. *Labium*: Length 1.18–1.22 mm, extending to near base of ovipositor. *Antenna*: Segment I, length 0.26 mm; II, 0.85–0.93 mm; III, 0.51–0.53 mm; IV, 0.43–0.45 mm. *Pronotum*: Length 0.34–0.37 mm, basal width 0.69–0.70 mm.

Brachypterous female (n = 3) (Fig. 37): Length to apex of hemelytron 1.80–1.90 mm; length to base of cuneus 1.55–1.60 mm; length to apex of abdomen 2.20–2.40 mm; width across hemelytra 0.64–0.70 mm. *Head*: Length 0.35–0.40 mm, width across eyes 0.54–0.58 mm, interocular width 0.29 mm. *Labium*: Length 1.10–1.14 mm, extending to abdominal segment II. *Antenna*: Segment I, length 0.26–0.29 mm; II, 0.82–0.94 mm; III, 0.51–0.56 mm; IV, 0.43–0.45 mm. *Pronotum*: Length 0.29–0.34 mm, basal width 0.51–0.59 mm.

Host. Adults and nymphs have been taken in large numbers on switch grass, *Panicum virgatum* L. cv 'Alamo' [Poaceae], infested with Delphacidae (A. G. Wheeler, pers. comm.).

Distribution. This species was described and known previously only from Guatemala (as *I. picea*) and Honduras (as *T. hondurensis*). Colombia, Costa Rica, Mexico, Panama, and the United States (Florida, Maryland, and South Carolina) represent new country records and considerable range extensions.

Discussion. Specimens of *T. piceus* from Colombia, Costa Rica, Honduras, Mexico, and Panama represent an expected distribution for a Central American species, but the recent detection of it in Florida, Maryland, and South Carolina in the United States is somewhat of a mystery. The eastern United States is relatively well collected, so it seems unlikely that early workers overlooked this unusual bug, given that other obscure species of the genus with similar habits, such as *Tytthus vagus* (Knight) and the tiny *T. alboornatus* (Knight), have been discovered. The most logical explanation is that *I. piceus* has been inadvertently introduced relatively recently and moved around on ornamental grasses, such the one A. G. Wheeler found serving as a host in the South Carolina Botanical Gardens.

I have examined the holotypes of *T. hondurensis* and *T. piceus* and find them conspecific.

Type material examined. **Holotype** ♂ (of *Isopropa picea*) (00162336) (OSU): GUATEMALA: Pt. Barios: 3/3/05 [J. S. Hine coll., as per Osborn and Drake, 1915],

Herbert Osborn collection. **Holotype** ♂ (of *T. hondurensis*) (00162205) (USNM): **HONDURAS: Atlantida: Lancetilla**, Aug 1701, Stadelmann.

Other specimens examined. COLOMBIA: Cundinamarca: Sasaima, 4.96638°N, 76.4375°W, 1221 m, 28 Aug 1965, J. A. Ramos, 1 ♀ (00161785) (USNM). **COSTA RICA: Cartago:** Pejibaye, 24 Mar 1987 - 25 Mar 1987, W. E. Steiner, 1 ♀ (00161786) (USNM). **Puntarenas:** El Palmar, Jan 1962, J. O. Harrison, 2 ♂♂ (00161449 - 00161450) (USNM). **MEXICO: San Luis Potosi:** Huichihayan, 25 Sept. 1938, L. J. Lipovsky, 1 ♂ (UK).

PANAMA: Cerro Jefe, 12 Mar. 1969, R. L. Fischer, elev. 2000 ft., 1 ♀ (00166062) (AMNH). **UNITED STATES: Florida: Miami-Dade Co.:** Coral Gables, Matheson Hammock, 10 May 1997, Vince Golias, sweeping, 1 ♀ (00161829) (USNM). **Maryland: Howard Co.:** Howard Co. field, 18 Oct 1961, collector unknown, red clover (Fabaceae), 1 ♂ (00161827) (USNM). **South Carolina: Pickens Co.:** South Carolina Botanical Garden, Clemson, 28 Aug 2004, A. G. Wheeler, Jr., *Panicum virgatum*, 1 ♀ (00161813) (Poaceae), 5 ♂♂ (00161814 - 00161818), 7 ♀♀ (00161819 - 00161825), 1 nymph (00161826) (USNM); 31 Jul 2005, A. G. Wheeler, Jr., *Panicum virgatum* (Poaceae), 11 ♂♂ (00161787 - 00161797), 15 ♀♀ (00161798 - 00161812) (USNM).

Tytthus pubescens (Knight)

Figs 38–40, 79–86, 171–174

Capsus geminus Flor 1860: 464 (orig. descrip.). Preoccupied by *Capsus geminus* Say, 1832 as noted by Henry and Wheeler 1988: 457.

Cyrtorhinus geminus: Reuter 1883: 382 (descrip.); Butler 1923: 480 (biol.); Wagner 1952: 129 (descrip., key).

Chlamydatius (*Cyrtorhinus*) *geminus*: Reuter 1875b: 126 (descrip.).

Cyrtorhinus pubescens Knight 1931: 172 (orig. descrip.). Synonymized by Carvalho and Southwood 1955: 28; resurrected by Henry and Wheeler 1988: 457.

Tytthus geminus: Fieber 1864: 83 (comb.); Carvalho and Southwood 1955: 28 (comb., descrip., distr., key); Kiritshenko 1951: 175 (key); Carvalho 1952: 81 (list); Carvalho 1958: 157 (cat.); Kerzhner 1964: 754 (key); Kelton 1980: 303 (descrip.host, distr.).

Tytthus geminus form *flori* Stichel 1956: 271 (orig. descrip.).

Tytthus geminus form *pallidior* Stichel 1956: 271 (orig. descrip.).

Tytthus pubescens: Henry and Wheeler 1988: 457 (cat., revised status); Wheeler and Henry 1992: 140 (distr., host); Polhemus 1994: 133 (list); Schuh 1995: 249 (cat.); Scudder 1997: 270 (distr., hosts); Kerzhner and Jovifov 1999: 442 (cat.); Maw et al. 2000: 121 (list); Wachman et al. 2004 (note, biol.); Wheeler 2011: 209 (distr., hosts).

Diagnosis. This species is distinguished by the fuscous to black head; brown to black pronotum, often entirely or with only the posterior angles or posterior half whitish to pale brown; the pale yellow to yellowish brown antennal segment I and black segments

Figures 171–178. Male genitalia **171–174** *T. pubescens* **171** left paramere **172** right paramere **173** endosoma **174** phallosome **175–178** *T. pygmaeus* **175** left paramere **176** right paramere **177** endosoma **178** phallosome.

II–IV; the long, erect setae in both sexes on antennal segment II as long or longer than the diameter of the segment; the uniformly pale, translucent hemelytra; and pale brownish yellow legs. Males of this species are always macropterous (Fig. 38); both macropters (Fig. 39) and brachypters (Fig. 40) are known for females, but brachypters are most common.

This Holarctic species is superficially similar to another Holarctic species, *Tyttthus pygmaeus*, in general color and size. *Tyttthus pubescens* is readily distinguished by the pale antennal segment I, the long erect and semierect setae on antennal segments I and II, and the often pale humeral pronotal angles.

Description. *Macropterous male* (n = 10) (Figs 38, 79, 80): Length to apex of hemelytron 2.59–3.01 mm, length to base of cuneus 1.98–2.37 mm, width across hemelytra 0.93–0.96 mm. *Head*: Length 0.30–0.32 mm, width across eyes 0.64–0.66 mm, interocular width 0.30–0.32 mm. *Labium*: Length 1.01–1.07 mm. *Antenna*: Seg-

ment I length 0.35–0.38 mm, II 0.88–0.94 mm, III 0.62–0.66 mm, IV 0.56–0.58 mm. *Pronotum*: Length 0.35–0.40 mm, basal width 0.74–0.78 mm.

Coloration: Head (Figs 81–83): Fuscous to black, with a small, yellow, interocular spot near inner margin of each eye; eyes reddish brown. *Labium*: Segments I–III pale yellow; segment IV brown. *Antenna*: Segment I pale yellow; segment II–IV fuscous to black. *Pronotum*: Uniformly fuscous to black, some specimens brown at posterior angles, others pale brown on posterior half, sometimes with dark brown invading darker anterior half. *Mesoscutum and Scutellum*: Fuscous to black. *Hemelytra*: Pale translucent yellow to whitish. *Ostiolar evaporative area* (Fig. 84): Fuscous to black. *Ventral surface*: Thorax and abdomen uniformly fuscous to black. *Legs*: Coxae pale yellow, the bases brown; femora, tibiae, tarsi, and claws (Fig. 86) uniformly pale yellow.

Structure, texture, and vestiture: Head: Weakly shiny, impunctate; set with relatively long, erect and semierect setae on vertex and frons. *Labium*: Extending to apices of meso- or bases of metacoxae; segment I extending just past base of head to anterior margin of xyphus before procoxae. *Antenna*: Segment I set with rather short, sparse, recumbent setae and two to four or more long, erect, subapical, bristlelike setae; segment II densely set with short, recumbent setae, intermixed with erect and semierect setae mostly subequal in length to diameter of segment. *Pronotum*: Nearly rectangular; anterior angles rounded; lateral margins straight, only slightly widening to posterior angles; posterior margin straight or only very slightly sinuate; set with relatively long, recumbent and semierect setae. *Mesoscutum*: Broadly exposed, even in brachypters; with a few scattered, semierect setae. *Scutellum*: weakly shiny, equilateral; set with relatively long, semierect setae. *Hemelytron*: Macropterous, subparallel; cuneus and membrane fully developed, extending beyond apex of abdomen; evenly set with recumbent setae.

Male genitalia (Fig. 85): *Left paramere* (Fig. 171): Right arm broad, widened through middle, tapering to a fine point apically; left arm short, apically pointed. *Right paramere* (Fig. 172): Elongate oval. *Endosoma* (Fig. 173): Strongly C-shaped, apically blunt. *Phallosome* (Fig. 174): Broad, apically acute.

Macropterous female (n = 10) (Fig. 39): Length to apex of hemelytron 2.66–3.10 mm, length to base of cuneus 1.98–2.24 mm, width across hemelytra 1.06–1.15 mm. *Head*: Length 0.30–0.32 mm, width across eyes 0.64–0.67 mm, interocular width 0.32–0.34 mm. *Labium*: Length 1.12–1.15 mm. *Antenna*: Segment I length 0.29–0.30 mm, II 0.69–0.72 mm, III 0.51–0.54 mm, IV 0.48–0.51 mm. *Pronotum*: Length 0.35–0.38 mm, basal width 0.82–0.93 mm.

Macropters have normally developed hemelytra that extend well beyond the apex of the abdomen as in males. Out of 63 females examined, only 10 are macropterous.

Brachypterous female (n = 10) (Fig. 40): Length to apex of abdomen 2.34–2.66 mm, length to base of cuneus 2.05–2.11 mm, width across hemelytra 0.94–1.15 mm. *Head*: Length 0.32–0.34 mm, width 0.67–0.69 mm, interocular width 0.32–0.34 mm. *Labium*: Length 1.10–1.17 mm. *Antenna*: Segment I length 0.27–0.32 mm, II 0.75–0.80 mm, III 0.50–0.54 mm, IV 0.45–0.53 mm. *Pronotum*: Length 0.40–0.42 mm, basal width 0.75–0.83 mm.

Brachypters are broadly rounded, with the cuneus sometimes slightly shortened and membrane greatly reduced and not attaining the apex of the abdomen.

Host. In North America, this species has been collected on *Carex* sp. (Kelton 1980) and *Carex utriculata* Boott [Cyperaceae] (Wheeler 2011). It has been taken on rushes, sedges, and grasses in England where it is said to prey on leafhopper eggs (Butler 1923, Southwood and Leston 1959, Rothschild 1963, Wheeler and Henry 1992). Specimens from Arizona were beaten from clumps of deer grass, *Muhlenbergia rigens* (Benth.) Hitchc. [Poaceae].

Distribution. This Holarctic species was previously known in North America from Alaska, Alberta, British Columbia, Colorado, Newfoundland, New Mexico, Quebec, Saskatchewan, and Yukon Territory (Henry and Wheeler 1988, Wheeler and Henry 1992, Polhemus 1994, Maw et al. 2000, Wheeler 2011). Arizona is a new state record.

In the Old World, it is known in Asia from Russia (East Siberia, Far East, and West Siberia) and in northern Europe from Austria, Byelorussia, Czech Republic, Denmark, Estonia, Finland, France, Great Britain, Germany, Hungary, Ireland, Latvia, Luxembourg, Moldavia, The Netherlands, Norway, Poland, Russia (Central European and Northern European territories), Slovakia, Sweden (Wheeler and Henry 1992, Kerzhner and Josifov 1999).

Type material examined. Holotype ♀ (brachypterous) of *T. pubescens* (USNM) **UNITED STATES: Colorado:** Wray, 4 Aug 1925, H. H. Knight (USNM).

Wheeler, Jr., *Carex utriculata* (Cyperaceae), 4 ♂♂ (00162184 - 00162187) (USNM). Valles Caldera National Preserve, below historic ranch headquarters, 35.86363°N, 106.51681°W, 17 Aug 2009 - 18 Aug 2009, A. G. Wheeler, Jr., *Carex utriculata* (Cyperaceae), 7 ♂♂ (00162177 - 00162183), 13 ♀♀ (00162164 - 00162176) (USNM).

***Tytthus pygmaeus* (Zetterstedt)**

http://species-id.net/wiki/Tytthus_pygmaeus

Figs 41–44, 175–178

Capsus pygmaeus Zetterstedt 1838: 279 (orig. descrip.). Lectotype designated by Carvalho and Southwood 1955: 24.

Capsus pellucens Boheman 1852: 75 (orig. descrip.). Synonymized by Sahlberg 1868: 176.

Tytthus insignis Douglas and Scott 1866: 247 (orig. descrip.). Synonymized by Saunders 1876: 113.

Capsus (Cyrtorhinus) pygmaeus Thomson 1871: 437 (key).

Leptomerochoris insignis: Walker 1873: 131 (list).

Tytthus pygmaeus: Fieber 1864: 83 (descrip.); Carvalho and Southwood 1955: 23 (descrip., key); Carvalho 1958: 158 (cat.); Kerzhner 1964: 754 (key); Kelton 1980: 289 (distr., host); Kerzhner 1988: 840 (key); Henry and Wheeler 1988: 458 (cat.); Wheeler and Henry 1992: 141 (distr., host); Schuh 1995: 250 (cat.); Scudder 1997: 271 (distr., hosts); Kerzhner and Josifov 1999: 442 (cat.); Wachmann et al. 2004: 271 (note, biol., host, photo); Wheeler 2011: 210 (distr., hosts).

Chlamydatus pygmaeus Reuter 1875a: 31 (key); 1875b: 282 (descrip.).

Cyrtorhinus pygmaeus: Reuter 1883: 554 (descrip., key); Saunders 1892: 283 (descrip., hosts); Van Duzee 1917: 824 (cat.); Butler 1923: 480 (biol.); Kiritschenko 1951: 175 (key); Wagner 1952: 128 (descrip., key).

Tytthus pygmaeus form *flavomarginata* Stichel 1956: 272 (orig. descrip.). Synonymized by Schuh 1995: 249

Tytthus pygmaeus form *flavescens* Stichel 1956: 272 (orig. descrip.). Synonymized by Schuh 1995: 249.

Tytthus vagus: Polhemus 1994: 133 (list). See discussion under *T. vagus*.

Diagnosis. This highly variable species is distinguished by the black head, with relatively vague interocular spots; entirely pale (European material) to entirely fuscous to black (all North American material) pronotum, with intermediate color forms; very clear or translucent white hemelytra; the fuscous to black antennal segment I, with the apical one fourth pale yellow; antennal segments II–IV uniformly fuscous to black; and the uniformly pale yellow legs. All males and most females of this species are fully macropterous; only a few weakly brachypterous females, with the membrane extending to the apex of the abdomen, have been examined.

Tytthus pygmaeus is superficially similar to the Holarctic *T. pubescens* in overall size, coloration, and distribution. It can be distinguished from *T. pubescens* by the fuscous antennal segment I having only the apex pale, the short, recumbent setae on antennal segments I and II, and the variably fuscous to pale pronotum (but never fuscous with pale humeral angles as in *T. pubescens*).

Description. *Male* (n = 10) (Figs 41, 43): Length to apex of hemelytron 2.50–2.94 mm, length to base of cuneus 1.98–2.14 mm, width across hemelytra 0.94–0.98 mm.

Head: Length 0.29–0.32 mm, width across eyes 0.69–0.75 mm, interocular width 0.30–0.32 mm. *Labium*: Length 1.07–1.12 mm. *Antenna*: Segment I length 0.30–0.32 mm, II 0.98–1.04 mm, III 0.61–0.62 mm, IV 0.54–0.58 mm. *Pronotum*: Length 0.35–0.40 mm, basal width 0.77–0.82 mm.

Coloration: *Head*: Shiny fuscous to black, with a relatively small, yellow, interocular spot near inner margin of each eye; eyes fuscous to dark reddish brown. *Labium*: Uniformly pale yellow, with apex of segment IV usually brown. *Antenna*: Segment I, fuscous to black, with only apical one fourth to one third pale yellow; segment II–IV black. *Pronotum*: Highly variable, ranging from uniformly pale yellow to entirely fuscous to black, with many intermediate forms, including all of disc dark and anterior half yellow and almost entirely dark with yellow across anterior margin and through middle of calli; some yellow specimens with only fuscous posterior angles. *Mesoscutum and Scutellum*: Uniformly fuscous to black. *Hemelytron*: Uniformly clear to very pale translucent white. *Ostiole*: Fuscous to black, even on palest specimens. *Ventral surface*: Thorax uniformly fuscous; abdomen fuscous along lateral margins and genital capsule, ventral area and sides pale yellow to whitish. *Legs*: Uniformly pale yellow.

Structure, texture, and vestiture: *Head*: Shiny, impunctate, much broader than long; set with numerous, long, erect and semierect setae on vertex and frons. *Labium*: Extending to apices of meso- or bases of metacoxae; segment I extending just beyond head to anterior margin of xyphus just before procoxae. *Antenna*: Segment I sparsely set with recumbent setae and two, long, erect, subapical, bristlelike setae; segment II, thickly set with short, recumbent and semierect setae. *Pronotum*: Trapeziform, anterior angles nearly weakly rounded; lateral margins straight, gradually widening to posterior angles; posterior margin nearly straight or only weakly sinuate. *Mesoscutum*: Broadly exposed. *Scutellum*: Equilateral; sparsely set with scattered relatively short, semierect setae. *Hemelytra*: Macropterous, cuneus and membrane fully developed, extending well beyond apex of abdomen; evenly set with recumbent setae.

Male genitalia: *Left paramere* (Fig. 175): Right arm long, broad, apically blunt; left arm short, apically pointed. *Right paramere* (Fig. 176): Elongate oval. *Endosoma* (Fig. 177): Strongly C-shaped, apically blunt. *Phallosome* (Fig. 178): Slender, apically acute.

Female (n = 10) (Figs 42, 44): Length to apex of hemelytron 2.92–3.17 mm, length to base of cuneus 2.21–2.34 mm, width across hemelytra 1.20–1.31 mm. *Head*: Length 0.34–0.35 mm, width across eyes 0.74–0.75 mm, interocular width 0.34–0.35 mm. *Labium*: Length 1.12–1.20 mm. *Antenna*: Segment I length 0.27–0.29 mm, II 0.86–0.88 mm, III 0.61–0.62 mm, IV 0.54–0.58 mm. *Pronotum*: Length 0.40–0.42 mm, basal width 0.91–0.96 mm.

Hosts. In North America, this species has been recorded from sedges, *Carex* spp. (Kelton 1980) and *Carex urticulata* [Cyperaceae] (Wheeler 2011). In the Old World, it has been taken on European beachgrass, *Ammophila arenaria* (L.) Link [Poaceae], and on rushes, *Juncus* spp., where it feeds on the delphacid *Conomelus anceps* (Germar) (Scudder 1957, Wheeler and Henry 1982). Rothschild (1963) studied the biology and illustrated the fifth instar. Ehanno (1987) studied the life history in France and

reported *Juncus effusus* L. (as *conglomeratus* L.) [Juncaceae] and *Typha* sp. [Typhaceae] as hosts.

Distribution. This Holarctic species is known in Canada from Alberta, British Columbia, Labrador, Newfoundland, Ontario, Saskatchewan, and Yukon Territory and in the United States from New Mexico and Wyoming (Kelton 1980, Henry and Wheeler 1988, Wheeler and Henry 1992, Maw et al. 2000, Wheeler 2011). Colorado is a new state record.

In the Old World, it is known in Asia from Russia (East Siberia, Far East, and West Siberia) and in Europe from Austria, Byelorussia, Czech Republic, Denmark, Estonia, Finland, France, Germany, Hungary, Latvia, Luxembourg, Moldavia, The Netherlands, Norway, Poland, Russia (Central European and North European territories), Slovakia, Sweden, and the United Kingdom (Carvalho and Southwood 1955, Wheeler and Henry 1992, Kerzhner and Josifov 1999).

***Tytthus uniformis* Henry, sp. n.**

urn:lsid:zoobank.org:act:682B99D0-90E6-45BE-8565-BC96CDBAA1D9

http://species-id.net/wiki/Tytthus_uniformis

Figs 45–47, 87–100, 179–182

Diagnosis. This species is distinguished by the contrasting black head and antennal segments I and II and the uniformly pale orange-brown pronotum and legs, and the slightly more smoky orange-brown hemelytra. All males are macropterous and all females examined, except two macropters, are brachypterous.

Tytthus uniformis is most similar in overall appearance to *T. balli* and *T. insperatus*. It can be distinguished from *T. balli* by uniformly brownish-orange pronotum and hemelytra; *T. balli* is usually infuscated on the posterior half of the pronotum, and the inner half of the clavus and apical third of the corium are dark brown. It is distinguished from *T. insperatus* by the uniformly pale orange pronotum and legs; *T. insperatus* has a dark brown pronotum, each femur has a narrow dorsal and lateral red stripe, and the hind tibiae are fuscous.

Description. *Macropterous male* (n= 10, plus holotype in parentheses) (Figs 45, 87, 88): Length to apex of hemelytron 2.45–2.60 mm (2.25 mm); length to base of cuneus 1.70–1.78 mm (1.68 mm); width across hemelytra 0.74–0.77 mm (0.74 mm). *Head:* Length 0.30–0.32 mm (0.30 mm), width across eyes 0.51–0.53 mm (0.51 mm); interocular width 0.29–0.30 mm (0.27 mm). *Labium:* Length 0.94–1.01 mm (0.90 mm). *Antenna:* Segment I, length (0.37 mm (0.34 mm)); II, 1.17–1.20 mm (left 0.91 mm, right 1.06 mm); III, 0.67–0.69 mm (0.64 mm); IV, 0.42–0.43 mm (0.40 mm). *Pronotum:* Length 0.27 mm (0.24 mm), basal width 0.64–0.69 mm (0.67 mm).

Coloration: *Head* (Figs 89–91): Semishiny fuscous to black, pale spot on either side of vertex obsolete or indistinct. *Labium:* *Antenna:* Uniformly black, segment I very narrowly pale at apex on some specimens. *Pronotum:* Uniformly pale brownish orange, posterior angles sometimes slightly infuscated; collar pale or whitish; mesoscutum and scutellum uniformly pale brownish orange. *Hemelytron:* Uniformly pale, translucent, brownish orange; membrane translucent smoky brown. *Ostiole evaporative area* (Fig. 92): Brownish orange to orange. *Ventral surface:* Thoracic segments orange to reddish orange; abdomen in males reddish orange dorsally, paler orange ventrally, with genital capsule becoming fuscous or black; abdomen in females infuscated dorsally, gradually fading to pale orange ventrally. *Legs:* Uniformly pale brownish orange; claw (Fig. 94).

Structure, texture, and vestiture: Head: Wider than long, interocular width subequal to length, impunctate, semishiny; set with a few, scattered, erect, nearly bristlelike dark setae. *Labium:* Extending beyond metacoxae to base of abdomen. *Pronotum:* About 2.5 times as wide at base as long, lateral margins weakly concave, posterior margins moderately flared; set with short, semierect and recumbent setae. *Mesoscutum:* Broadly exposed. *Scutellum:* Slightly wider across base than on sides; set with short, semierect and recumbent setae. *Hemelytron:* Entire in males, cuneus nearly three times as long as wide at base, membrane fully developed, extending well beyond apex of abdomen; set with short, semierect and recumbent setae.

Male genitalia (Fig. 93): *Left paramere* (Fig. 179): Mitt-shaped; right arm long, slender, apically crenulate; left arm short, apically acute. *Right paramere* (Fig. 180): Oval. *Endosoma* (Fig. 181): Strongly C-shaped, apex bluntly pointed. *Phallosome* (Fig. 182) slender, apically pointed.

Macropterous female (n= 2) (Fig. 46): Length to apex of hemelytron 2.65–2.75 mm, length to base of cuneus 1.88–2.00 mm, width across hemelytra 0.91–1.08 mm. *Head:* Length 0.32–0.34 mm, width across eyes 0.54 mm; interocular width 0.32 mm. *Labium:* Length 0.96–0.98 mm, extending to bases of hind coxae. *Antenna:* Segment I, length 0.34–0.35 mm, II 0.99–1.07 mm; III 0.74–0.77 mm; IV 0.50–0.51 mm. *Pronotum:* Length 0.30 mm, basal width 0.75 mm.

Brachypterous female (n= 8) (Figs 47, 95–100): Length to apex of abdomen 1.90–2.23, length to base of cuneus 1.63–1.75 mm, width across hemelytra 0.90–0.93 mm. *Head:* Length 0.34–0.35 mm, width across eyes 0.54–0.56 mm; interocular width 0.34 mm. *Labium:* Length 0.96–0.98 mm, extending to second or third visible abdominal segment. *Antenna:* Segment I, length 0.30–0.32 mm; II, 0.94–1.04 mm; III, 0.40–0.42 mm; IV, 0.40–0.45 mm. *Pronotum:* Length 0.26–0.27 mm, basal width 0.62–0.67 mm.

The hemelytra are abbreviated in nearly all females examined. The cuneal fracture is visible but the cuneus is greatly shortened, with only the narrow basal area of membrane along abbreviated cuneus present.

Etymology. Named for the uniformly pale brownish-orange pronotum, hemelytra, and legs.

Host. Big sacaton, *Sporobolus wrightii* Munro ex Scribn. [Poaceae].

Distribution. United States: Arizona and New Mexico.

Type material. **Holotype** ♂ (00162002) (USNM): **UNITED STATES: New Mexico: Hidalgo Co.:** Rt 338, 26.3 km S of Animas, 31.71636°N, 108.82239°W, 1457 m, 15 May 2004, A. G. Wheeler, Jr., *Sporobolus wrightii* (Poaceae). **Paratypes:** **UNITED STATES: Arizona: Cochise Co.:** Huachuca Mountains, 5354 Ash Canyon Road, 0.5 mi W of Hwy 92, 31.38194°N, 110.22444°W, 1554 m, 17 Aug 1992, N. McFarland, 1 ♀ (00162047) (USNM). **Santa Cruz Co.:** Audubon Research Ranch, SE of Elgin, 12 - 14 May 2004, A. G. Wheeler, Jr., *Sporobolus wrightii* (Poaceae), 9 ♂♂ (00162021, 00162033 - 00162039, 00162046), 17 ♀♀ (00162022 - 00162032, 00162040 - 00162045) (USNM). **New Mexico: Hidalgo Co.:** Rt 338, 26.3 km S of Animas, 31.71636°N, 108.82239°W, 1457 m, 15 May 2004, A. G. Wheeler, Jr., *Sporobolus wrightii* (Poaceae), 4 ♂♂ (00162033 - 00162036) (USNM).

***Tytthus vagus* (Knight)**

http://species-id.net/wiki/Tytthus_vagus

Figs 48, 49, 101–108, 183–186

Cyrtorhinus caricis var. *vagus* Knight 1923: 511 (orig. descrip.).

Cyrtorhinus caricis vagus: Blatchley 1926: 853 (descrip., key).

Cyrtorhinus vagus: Knight 1927a: 40 (list).

Tytthus vagus: Carvalho and Southwood 1955 (descrip., n. comb.); Carvalho 1958: 159 (cat.); Henry and Wheeler 1988: 458 (cat.); Schuh 1995: 250 (cat.); Maw et al. 2000: 121 (list).

Diagnosis. This species is distinguished by the black head, pronotum, and scutellum; black antennae; dark translucent smoky brown hemelytra; and pale yellowish brown

legs, with the hind femora infuscated on the distal third to one half. All known specimens are macropterous.

Tytthus vagus is similar to *T. femoralis* in having dark antennae, pale infuscated hemelytra, and apically infuscated hind femora. It is readily distinguished from *T. femoralis* in lacking distinct fuscous knee spots on the tibiae. It keys out with *T. panamensis* and *T. juturnaiba*, but is separated by the combination of dark antennae and infuscated hind femora.

Description. *Macropterous male* (n = 10, plus holotype in parentheses) (Figs 48, 101, 102): Length to apex of hemelytron 2.56–2.92 mm (2.75 mm), length to base of cuneus 1.18–2.03 mm (2.00 mm), width across hemelytra 0.85–0.96 mm (0.90 mm). *Head*: Length 0.27–0.35 mm (0.30 mm), width across eyes 0.61–0.66 mm (0.59 mm), interocular width 0.30–0.34 mm (0.30 mm). *Labium*: Length 0.88–0.90 mm (0.75 mm). *Antenna*: Segment I length 0.30–0.34 mm (0.34 mm), II 0.83–0.90 mm (0.85 mm), III 0.56–0.61 mm (missing), IV 0.42–0.50 mm (missing). *Pronotum*: Length 0.30–0.32 mm (0.32 mm), basal width 0.75–0.80 mm (0.80 mm).

Coloration: *Head* (Figs 103–105): Uniformly, shiny black, with a distinct, yellow, interocular spot near inner margin of each eye; eyes dark reddish brown; scattered with relatively long, semierect and erect setae. *Labium*: Pale yellow, with apical half of segment IV dark brown. *Antenna*: Segment I fuscous or black, with only apex narrowly pale or yellowish; segments II fuscous to black, with a very narrow pale ring at base; segment III and IV uniformly fuscous. *Pronotum*: Uniformly shiny black. *Mesoscutum*: Fuscous to black. *Scutellum*: Fuscous to black. *Hemelytron*: Dark translucent, smoky brown, becoming darker on clavus. *Ostiole area* (Fig. 107): Uniformly fuscous. *Ventral surface*: Thorax and abdomen uniformly fuscous to black. *Legs*: Coxae brown, with only the apices pale; fore and middle coxae uniformly pale yellow, hind coxa yellow with a broad dark brown to fuscous, subapical band; tibiae, tarsi, and claws (Fig. 108) uniformly pale yellow.

Structure, texture, and vestiture: *Head*: Uniformly shiny, impunctate, broader than long; buccula relatively narrow, extending posteriorly to near hind margin of eye; set with long, erect and semierect, brown setae. *Labium*: Extending to middle coxae; segment I extending to anterior edge of prosternum. *Antenna*: Segment I with numerous, short, recumbent, brown setae and two, long, erect, black, bristlelike setae subapically; segment II thickly set with short, semierect, brown setae. *Pronotum*: Shiny, impunctate, calli weakly swollen; anterior angles rounded, lateral margins weakly concave, weakly flaring at posterior angles; posterior margin weakly sinuate, almost straight; thickly set with short, semierect, brown setae. *Mesoscutum*: Shiny, impunctate, broadly exposed; with a few scattered, semierect, brown setae. *Scutellum*: Shiny, impunctate, with scattered, semierect, brown setae. *Hemelytron*: Macropterous, subparallel when paired, with fully developed cuneus and membrane, extending well beyond apex of abdomen; evenly clothed with semierect and recumbent, pale brown setae..

Male genitalia (Fig. 107): *Left paramere* (Fig. 183): Mitt-shaped, right arm long, broad, and apically rounded; left arm short, slender, and apically acute. *Right paramere*

(Fig. 184): Round to weakly oval. *Endosoma* (Fig. 185): C-shaped, bluntly rounded apically. *Phallotheca* (Fig. 186): Slender, apically acute.

Macropterous female (n = 10) (Fig. 49): Length to apex of hemelytron 2.80–3.12 mm, length to base of cuneus 2.00–2.28 mm, width across hemelytra 1.07–1.15 mm. *Head*: Length 0.29–0.32 mm, width across eyes 0.59–0.67 mm, interocular width 0.32–0.37 mm. *Labium*: Length 0.93–0.96 mm, extending to bases of middle coxae. *Antenna*: Segment I length 0.27–0.32 mm, II 0.72–0.77 mm, III 0.51–0.56 mm, IV 0.45–0.48 mm. *Pronotum*: Length 0.32–0.35 mm, basal width 0.82–0.90 mm.

Hosts. Taken by A. G. Wheeler on *Spartina alterniflora* and *Spartina bakeri* [Poaceae]. One specimen, collected on trumpet creeper, *Campsis radicans* (L.) Seem ex Bureau [Bignoniaceae], undoubtedly, represents an accidental or sitting record. Denno (in litt, 2005) informed me that *T. vagus* was abundant only on *S. alterniflora* in Tuckerton, New Jersey, whereas the sympatric *T. alboornatus* was found only on *S. patens*. See Döbel and Denno (1994), Finke and Denno (2003, 2005), Denno et al. (2006) and papers cited therein for in-depth studies on of *T. vagus* and its impact as a predator on delphacid populations on *S. alterniflora*.

Distribution. This coastal species is known in Canada from New Brunswick, Newfoundland, and Nova Scotia, and in the United States from Louisiana, Maryland, North Carolina, New Jersey, New York, and Virginia (Knight 1923; Lindberg 1958, Henry and Wheeler 1988, Maw et al. 2000). Polhemus (1994) reported *T. vagus* from Larimer County, Colorado, but this record certainly is an error for another species, probably the Holarctic *T. pygmaeus*, a similar-appearing species with dark antennae.

New state records reported herein are Connecticut, Delaware, Florida, Massachusetts, Mississippi, and South Carolina.

Type material examined. Holotype: ♂ (00162339) (USNM): **UNITED STATES: New York: Queens Co.:** Rockaway Beach, Long Island, 40.57138°N, 73.85138°W, 10 Sep 1917, W. A. ***Tytthus wheeleri* Henry, sp. n.**

urn:lsid:zoobank.org:act:1F707E19-3E1C-4A47-BD13-E3027DB5756E

http://species-id.net/wiki/Tytthus_wheeleri

Figs 1, 50–52, 187–190

Diagnosis. This species, known from brachypterous males and females (Figs 50, 52) and only one macropterous female (Fig. 51), is distinguished by the small size, overall dark brown coloration with only the basal third of the corium and clavus pale or white, the dark brown antennal segment I, and pale yellowish-brown tibiae.

It is similar to *T. montanus* in overall brown coloration with the basal area of the corium and clavus pale, but is distinguished from that species by the much smaller size, dark antennal segment I, and pale tibiae. It is also similar to *T. alboornatus* in overall coloration, but differs in lacking a narrow pale area across the apex of the corium and the dark antennal segment I and pale segment II. All specimens of *T. wheeleri* at hand, except one macropterous female, are strongly brachypterous and lack a cuneus and membrane on each hemelytron.

Description. *Brachypterous male* (n= 10; holotype in parentheses) (Fig. 50): Length to apex of abdomen 1.08–1.28 mm (1.30 mm); length to base of cuneus 0.95–1.05 mm (1.05 mm); width across hemelytra 0.51–0.61 mm (0.56 mm). *Head:* Length 0.24–0.29 mm (0.26 mm), width across eyes 0.43–0.45 mm (0.43 mm); interocular width 0.26–0.29 mm (0.27 mm). *Labium:* Length 0.75–0.77 mm (0.80 mm). *Antenna:* Segment I, length 0.22–0.27 mm (0.26 mm); II, 0.75–0.82 mm (0.83 mm); III, 0.45–0.48 mm (0.51 mm); IV, 0.34–0.40 mm (0.32 mm). *Pronotum:* Length 0.19–0.21 mm (0.21 mm), basal width 0.40–0.48 (0.43 mm).

Macropterous male: Unknown.

Coloration: Overall coloration dark brown. *Head:* Dark shiny brown, becoming paler yellowish brown ventrally, yellow spot on inner margin of each eye absent; eyes fuscous, often with a reddish tinge. *Antenna:* Segment I dark brown; II, pale yellowish brown, sometimes weakly red tinged at apex; III and IV pale yellowish brown. *Pronotum:* Dark shiny brown; scutellum dark shiny brown with apical half to one third pale yellowish brown. *Hemelytron:* Dark brown pale translucent yellowish brown to whitish on basal one third to half of corium. *Ventral surface:* Thorax dark brown, usually red tinged; ostiolar auricle brown, often red tinged; abdomen dark brown laterally, becoming paler

ventrally, often tinged with red at base. *Legs*: Uniformly pale yellowish brown, except for dark brown hind femora with basal third and narrow apex pale yellowish brown.

Structure, texture, and vestiture: *Head*: Wider than long, impunctate, eyes prominent, frons swollen, interocular width much greater than combined dorsal diameter of eyes. *Labium*: Extending just past metacoxae to base of abdomen. *Pronotum*: Impunctate, at most with only a few fine punctures across middle; rectangular, wider than long, lateral margins nearly straight, posterior margin weakly sinuate in brachypterous forms; lateral margins concave, posterior angles widely flared in macropterous form; calli weakly developed; scutellum impunctate, equilateral. *Hemelytron*: Strongly brachypterous in all but one specimen; corium and clavus fused (claval suture absent), membrane and cuneus absent, remaining corium weakly rounded laterally, truncate posteriorly. Hemelytron of only known macropter with fully developed clavus, cuneus, and membrane having two closed cells. Pubescence short, sparse, with several erect, bristlelike setae on head along basal margin, inner margin of eyes, and on frons.

Male genitalia: *Left paramere* (Fig. 187): Mitt-shaped; right arm long, stout, apically bluntly rounded; left arm short, apically acute. *Right paramere* (Fig. 188): Rounded. *Endosoma* (Fig. 189): S-shaped, apically acute. *Phallosome* (Fig. 190): Slender, apically acute.

Macropterous female (n= 1) (Fig. 51): Length to apex of hemelytron 1.80 mm, length to base of cuneus 1.27 mm, width across hemelytra 0.62 mm. *Head*: Length 0.26 mm, width across eyes 0.42 mm; interocular width 0.27 mm. *Labium*: Length 0.83. *Antenna*: Segment I, length 0.22 mm; II, 0.62 mm; III, 0.43 mm; IV, 0.27 mm. *Pronotum*: Length 0.24 mm, basal width 0.59 mm.

Brachypterous female (n= 10) (Fig. 52): Length to apex of abdomen 1.48–1.68 mm, length to apex of hemelytron 1.23–1.30 mm, width across hemelytra 0.70–0.74 mm. *Head*: Length 0.26–0.34 mm, width across eyes 0.46 mm; interocular width 0.29–0.30 mm. *Labium*: Length 0.93–0.96 mm. *Antenna*: Segment I, length 0.22–0.26 mm; II, 0.72–0.77 mm; III, 0.48–0.54 mm; IV, 0.37–0.40 mm. *Pronotum*: Length 0.21–0.22 mm, basal width 0.48–0.51 mm.

Etymology. This species is named after my good friend and colleague, Dr. Alfred G. Wheeler, Jr. (Department of Entomology, Clemson University, Clemson, South Carolina), who discovered and collected all but a few specimens of this very tiny, attractive new species. Dr. Wheeler's collections from grasses having well-developed crowns have yielded numerous new and interesting Heteroptera.

Hosts. Collected by A. G. Wheeler on the following hosts: big bluestem, *Andropogon gerardii* Vitman [Poaceae]; bushy bluestem, *Andropogon glomeratus* (Walt.) B. S. P.; bushy bluestem, *Andropogon tenuispathus* Nash [sometimes considered a synonym of *A. glomeratus* (Walt.) B. S. P. var. *pumilus* Vasey ex. L. H. Dewey]; Virginia beard grass, *Andropogon virginicus* L.; weeping love grass, *Eragrostis curvula* (Schrud.) Nees; gulf cordgrass, *Spartina spartinae* (Trin. Merr. ex Hitchc.; and paragrass, *Urochloa mutica* (Forssk.) T. Q. Nguyen [Poaceae].

Distribution. United States: Arkansas, Florida, Georgia, Kansas, Nebraska, South Carolina, Texas, and Virginia.

Figures 187–193. Male genitalia **187–190** *T. wheeleri* **187** left paramere **188** right paramere **189** endosoma **190** phallosome **191–193** *T. zwaluwenburgi* **191** left paramere **192** endosoma **193** phallosome.

Discussion. All specimens of this new species are brachypterous, except for one macropterous female collected in Highlands Co., Florida (March). That a macropterous female was discovered indicates that macropterous males eventually should be found. Given the small size and considering how difficult it is to collect this species from the crowns of certain bunch grasses, it is not surprising that few undetermined specimens of this species were found in collections.

The tiny brachypterous males (length 1.08–1.30 mm) rank *T. wheeleri* as possibly the smallest known species of Miridae.

***Tytthus zwaluwenburgi* Usinger**

http://species-id.net/wiki/Tytthus_zwaluwenburgi

Figs 53, 54, 191–193

Cyrtorhinus zwaluwenburgi Usinger 1944: 148 (orig. descrip.), 1951: 5 (key).

Tytthus zwaluwenburgi: Carvalho and Southwood 1955: 19 (descrip.); Carvalho 1958: 159 (cat.); Schuh 1984: 192 (diag., host), 1995: 250 (cat.).

Diagnosis. This species is readily distinguished by the uniformly yellow to testaceous coloration, except for the dark brown eyes and a vague brown area at the middle of the head.

Description. *Male* (n = 1 paratype) (Fig. 53): Length to apex of hemelytron 2.30 mm, length to base of cuneus 1.66 mm, width across hemelytra 0.77 mm. *Head*: Length 0.29 mm, width across eyes 0.56 mm, interocular width 0.30 mm. *Labium*: Length 0.74 mm. *Antenna* (missing; after Schuh 1984): Segment I length (not given), II 0.61 mm, III (not given), IV (not given). *Pronotum*: Length 0.27 mm, basal width 0.75 mm.

Coloration: Uniformly yellow to testaceous, except for the dark brown eyes and a vague brown area on the middle of the head.

Structure, texture, and vestiture (after Usinger 1944): Head half again as broad as long, 11.5: 8, smooth, shining, and strongly convex above. Eyes slightly less than half as wide as interocular space, 2.75: 6. First antennal segment shorter than interocular space, 5: 6, second segment three times as long as first, third and fourth segments broken off. Rostrum nearly reaching apices of middle coxae. Pronotum somewhat duller than head, clothed with short, sparse, decumbent hairs; broader across humeri than width of head, 15: 11.5, and less than half as long as broad, 6.5: 15; front margin shallowly concave, lateral margins feebly sinuate, and hind margin slightly concave. Scutellum longer than pronotum at middle, 7: 6, subdepressed, the disk very sparsely clothed with appressed hairs. Hemelytron simple, distinctly but sparsely clothed with appressed hairs; costal margin slightly, evenly arcuate. Legs slender, clothed with short, inconspicuous, pale hairs. Claws with simple hairlike setae rather than arolia.

Male genitalia (after Schuh 1984): *Left paramere* (Fig. 191): Mitt-shaped; right arm stout, broad, apically acute; left arm slender, apically acute. *Right paramere*: Not illustrated. *Endosoma* (Fig. 192): S-shaped. *Phallosome* (Fig. 193): Slender, bluntly rounded apically.

Female: (n = 1) (Fig. 54): Length to apex of hemelytron 2.53 mm, length to base of cuneus 1.80 mm, width across hemelytra 0.96 mm. *Head*: Length 0.29 mm, width across eyes 0.59 mm, interocular width 0.34 mm. *Labium*: Length 0.85 mm. *Antenna*: Segment I length 0.24 mm, II 0.61 mm, III and IV missing. *Pronotum*: Length 0.32 mm, basal width 0.80 mm.

Hosts. Recorded from *Boerhavia* sp. (Nyctaginaceae) by Usinger (1944) and Schuh (1984). Usinger (1944) noted that the various species of the genus prey on delphacid eggs, but since “delphacids have not been reported on Canton Island and since both

Cyrtorhinus and the cicadellid *Nesaloha cantonis* Oman were collected on *Boerhaavia*, it is possible that this new mirid is a predator on *Nesaloha*.”

Distribution. This species has been reported from Baker Island, Howland Island, and the Phoenix Islands (Canton Island) in the central Pacific (Usinger 1944, Schuh 1984).

Discussion. *Tytthus zwaluwenburgi* was described from only three specimens (holotype, paratype, and one teneral specimen). Schuh (1984) studied the holotype and illustrated the male genitalia.

Type material examined. Canton Island: 20 Nov 1940, R. Danner, 1 ♂ paratype (BPBM).

Other specimen examined. Baker Island: 18 Apr 1935, E. H. Bryan, Jr., 1 ♀ (BPBM). Phoenix Islands: Canton Island, 16 Mar 1924, E. H. Bryan, Jr., 1 ♀ (BPBM).

Phylogeny

Menard (2011) and Menard and Schuh (2011) have shown that *Tytthus* does not belong in Leucophoropterini based on both molecular sequence data and morphology and, thus, they transferred *Tytthus* to nominate tribe Phylini where it shows a relationship with several New World genera, including *Criocoris* Fieber, *Semium* Reuter, and *Spanagonicus* Berg. These findings are supported by Kelton's (1959) work that showed similarities in the male genitalia among these genera. The relationship of *Tytthus* to New World genera, the restriction to the Western Hemisphere of 17 of its 24 species, and the Holarctic distribution of two other species suggest a New World origin. Only the far-eastern *T. chinensis*, the Indo-Pacific *T. mundulus*, and *T. zwaluwenburgi* found on a few central Pacific islands are restricted to the Old World.

The morphology-based phylogeny of *Tytthus* presented here should be considered tentative because of the limited number of informative characters available to infer relationships. Although most species possess distinctions that allow relatively easy separation, characters, such as antennal, hemelytral, and leg coloration, are very homoplastic and did not offer much resolution. The male genitalia are relatively simple structures (e.g., Figs 109–116) and lack an apparent secondary gonopore, which is shared with several outgroup taxa, including species of the genera *Criocoris* Fieber and *Semium* Reuter (Kelton 1955, Menard 2011, Henry personal observ.). As a consequence, the matrix has fewer characters than taxa.

For this analysis, the matrix (Table 1) contained 27 species-group taxa and 23 characters, 17 of which were multistate. Characters (Table 2) were first processed using WinClada (Nixon 1999–2002) to run NONA (Goboloff 1999), using the default settings for the ratchet function. Three taxa (*T. chinensis*, *T. parviceps*, and *T. pygmaeus*) were scored polymorphic for pronotal coloration. Four characters (6, antennal segment II setae; 10, pronotal color; 13, hemelytral color; 19, knee spots) were scored additive because they reflected clear relationships among certain taxa, whereas homologies for all remaining characters were uncertain and, thus, scored as nonadditive. The genera *Criocoris*, *Plagiognathus* Fieber, and *Semium* were used as outgroups. The analysis with

The genus *Tytthus* is defined by a combination of the yellow spots on interocular area, bell-shaped or campanulate pronotum, simple S- or C-shaped endosoma, and host specificity (eggs of Delphacidae). In all trees (Figs 194–197), three monophyletic species groups were hypothesized: the *balli* group (*T. balli*, *T. insperatus*, and *T.*

Table 2. Characters and character states used in analysis of the genus *Tytthus*. The four left columns represent **1** character number **2** number of steps **3** consistency index, and **4** retention index. Character statistics are from one of nine trees (Fig. 194) generated by WinClada to run NONA using the ratchet function.

0.	2	50	50	Head shape: much broader than long (0); strongly rounded, bulbous (1).
1.	7	28	50	Interocular area adjacent to inner margin of each eye: unmarked (0); with a small yellow spot (1); with a large yellow spot (2).
2.	4	50	60	Clypeus: strongly protruding anteriorly (0); weakly protruding anteriorly, visible dorsally (1); rounded, not visible dorsally (2).
3.	12	33	38	Antennal segment I: uniformly dark brown or fuscous (0); dark brown or fuscous, with apical fourth to one third pale (1); pale at apex and base, with a broad fuscous band through middle (2); pale brownish yellow, with only base narrowly fuscous (3); uniformly pale (4).
4.	6	50	50	Antennal segment II: uniformly dark brown or fuscous (0); pale brownish yellow, with base fuscous (1); pale brownish yellow, with base and apex fuscous (2); uniformly pale brownish yellow (3).
5.	3	50	50	Antennal segment II: without specialized setae (0); males with erect, brushlike setae most prevalent along entire undersurface (1); male and females with long, erect setae as long as diameter of segment (2).
6.	8	12	30	Labium length: Extending to middle coxae or based of hind coxae (0); extending slightly beyond hind coxae on (1).
7.	6	33	55	Pronotal shape of macropters: trapeziform (0); lateral margins weakly concave, posterior angles moderately widened (1); lateral margin strongly concave, posterior angles strongly flared, companulate (2).
8.	4	25	0	Pronotal surface: not modified (0); with a distinct glaucous sheen on anterior lobe (1).
9.	7	57	72	Pronotum: Uniformly dark brown or fuscous (0); dark brown with anterior area around calli yellow (1); pale yellowish brown invaded with darker brown (2); pale orange, sometimes tinged with brown (3) uniformly pale yellow (4).
10.	2	50	0	Hemelytra: weakly to strongly convex laterally (0); straight or subparallel (1).
11.	3	66	66	Scutellum: Uniformly dark brown to fuscous (0); uniformly orange, sometimes with apex pale (1); uniformly pale yellowish green (2).
12.	6	50	80	Hemelytral color: Mostly dark, opaque (0); uniformly translucent white or yellowish to brownish white (1); translucent white, tinged with brown or darker areas on corium and clavus (2); largely dark brown, with base of corium and clavus and, sometimes, apex of corium pale (3).
13.	2	50	50	Hemelytral development in males: Fully macropterous (0); submacropterous, with membrane and cuneus abbreviated (1); staphylinoid or brachypterous, with membrane and cuneus absent, not extending to apex of abdomen (2).
14.	5	80	83	Fore femoral color: Uniformly dark brown or fuscous (0); dark brown with base and apex pale (1); pale (2); largely pale, with apex of infuscated (3); uniformly pale yellowish (4); uniformly pale orange (5).

15.	5	80	83	Middle femoral color: Uniformly dark brown or fuscous (0); dark brown with base and apex pale (1) pale (2); largely pale, with apex infuscated (3); uniformly pale yellowish (4); uniformly pale orange (5).
16.	6	66	80	Hind femoral color: Uniformly dark brown or fuscous (0); dark brown with base and apex pale (1); pale, invaded with infuscous (2); largely pale, with apices of all femora infuscated (3); uniformly pale yellowish (4); uniformly pale orange (5).
17.	7	57	75	Tibial color: Uniformly dark brown (0); uniformly pale yellowish brown (1); uniformly orange, sometimes with a short, narrow red basal stripe (2).
18.	5	40	40	Tibial knees: without fuscous knee spots (0); with fuscous knee spots (1) .
19.	5	40	25	Hind tibial spines: strong, dark (0); slender, reduced, usually pale (1); absent or indistinct, resembling surrounding setae (2).
20.	7	42	55	Endosoma shape: variably complex, not as in state 1, secondary gonopore distinct (0); weakly S-shaped, secondary gonopore absent (1); C-shaped, secondary gonopore absent (2).
21.	6	50	70	Left paramere: left arm slender (0); thickened, apically pointed (1); thickened, apically blunt (2); left arm greatly broadened, swordlike (3)
22.	1	100	100	Habits: species phytophagous, associated with specific host plants (0); species predatory, associated with specific Delphacidae (Auchenorrhyncha) (1)

uniformis), the *chinensis* group (*T. pymaeus*, *T. mundulus*, *T. pubescens*, *T. parviceps*, *T. chinensis*, and *T. mexicanus*), and the *alboornatus* group (*alboornatus*, *columbiensis*, *montanus*, and *wheeleri*). The *balli* group was defined by one synapomorphy, the pale orange pronotum (character 9, state 3). These species are also share a broad black head, a strongly campanulate pronotum, and orange or largely orange scutellum, hemelytra, and legs. The *chinensis* group was defined by one synapomorphy, the brushlike setae on antennal segment II (character 5, state 1), and the broad swordlike left arm of the left paramere (character 21, state 3). Within this group, *T. chinensis*, *T. mexicanus*, and *T. parviceps* shared the fuscous knee spots (character 18, state 1), found elsewhere only in *T. entrerianus* and *T. femoralis*. The *alboornatus* group was defined by one synapomorphy, the largely dark brown hemelytra with pale areas at the base and apex of the corium (character 12, state 3). Also, within this group, *T. alboornatus* and *T. wheeleri* possess the most extreme hemelytral brachyptery in the genus; brachyptery is found to a lesser extent in two other members of the group, *T. montanus*, and *T. piceus*, the latter of which falls outside the group. *Tytthus entrerianus* and *T. neotropicalis* always came out as sister species, based on two synapomorphies, the pale fore and middle femora (characters 14, state 2, ♀ character 15, state 2), as did *T. pallidus* and *T. piceus*, based on the color of the hemelytra (character 12, state 1) and the pale antennal segment I (character 3, state 3). *Tytthus zwaluwenburgi* is the most problematic species of the genus. Although it came out as the sister species to *T. amazonicus*, this relationship, supported only by color characters (character 3, state 4 ♀ character 9, state 2), is un-

Figures 194–197. Four resulting cladograms reflecting inferred *Tytthus* phylogeny generated by Winclada, running NONA, based on 27 taxa and 23 characters (Table 1), with character 17 deactivated. Black circles indicate nonhomoplasious characters; white circles indicate homoplasies; character number above branch, character state below.

Figures 198–200. Consensus trees generated by NONA and single cladogram, by TNT, based on 27 taxa and 23 characters (Table 1) **198** strict consensus tree based on nine cladograms generated by Winclada, running NONA, with all characters activated **199** strict consensus tree based on nine cladograms generated by Winclada, running NONA, with character 17 deactivated **200** single cladogram generated by Winclada, running the random addition sequence analysis by TNT, with character 17 deactivated. Black circles indicate nonhomoplasious characters; white circles indicate homoplasies; character number above branch, character state below.

likely to be correct. Its pale coloration and extreme isolation on islands in the central Pacific preclude any meaningful hypothesis about its relationship to other species. The characters for most remaining taxa exhibited considerably more homoplasy and, thus, their hypothesized position among the species was less stable.

The same character matrix (Table 1) as above, with 27 species-group taxa and 23 characters (with the same four characters scored as additive and character 17 deactivated), also was run using TNT (Goloboff et al. 2010). A first pass using the traditional analysis setting resulted in 29 trees with a length of 116, a ci of 46, and an ri of 60. An additional run using the random addition sequence function resulted in only one most parsimonious tree (Fig. 200), with a length of 109, a ci of 45, and an ri of 59. This tree was far more resolved than either of the above strict consensus trees (Fig. 198, 199) generated by Nona and most closely resembled tree number one (Fig. 194) of the four generated by Nona with character 17 deactivated. *Tytthus uniformis*, *T. balli*, and *T. insperatus* were hypothesized as a monophyletic group, as were *T. mundulus*, *T. pubescens*, *T. parviceps*, *T. chinensis*, and *T. mexicanus*. In sequence, *T. panamaensis* was hypothesized as sister to the remainder of the taxa, followed by the holoarctic *T. pygmaeus*. *Tytthus juturnaiba* and *T. vagus* formed a sister pair, as did *T. pallidus* and *T. piceus* and *T. enterianus* and *T. neotropialis*. Also, as in all of the previous analyses, *T. columbiensis*, *T. montanus*, *T. alboornatus*, and *T. wheeleri* formed a monophyletic group. The problematic *T. zwaluwenburgi* still grouped with *T. amazonicus*, a doubtful relationship.

As noted in my discussion of *T. chinensis* and *T. parviceps*, molecular data likely will help resolve some of the unclear relationships among the species of this intriguing genus of egg predators. If *T. juturnaiba* proves to be a junior synonym of *T. neotropialis*, the removal of that species and its conflicting character information should help reduce the level of homoplasy in certain characters and likely will yield a better hypothesis of relationships.

Acknowledgments

I am grateful to A. G. Wheeler, Jr. (Clemson University, Clemson, SC) for allowing me to study the considerable amount of U. S. material he collected, including that representing three new species; Charles Triplehorn (OSU) for lending the Osborn and Drake type of *Isoproba picea*; Michele Touchet (Systematic Entomology Laboratory [SEL], ARS, USDA, c/o USNM) for the color plates; Randall T. Schuh (AMNH), Robert Footitt and Michael D. Schwartz (CNC), Shephard Myers (BPM), S. H. Lee and R. K. Duwal (SNU), and R. S. Zack (WSU) for lending numerous important specimens from their institutions and, in the case of Dr. Schuh, numerous specimens borrowed from other institutions (as noted in the text) through the auspices of the Planetary Biodiversity Program (PBI); Michael Wilson (NMW) and Mick Webb (BMNH) for allowing me to visit and study material in their collections; the late Robert F. Denno (Department of Entomology, University of Maryland, College Park) for sharing observations on two species of *Tytthus* and for sending reprints his papers involving these predators; Katrina Menard

(Sam Noble Museum, University of Oklahoma, Norman) for sharing her preliminary phylogenetic data on Leucophoropterini and the position of *Tyttthus*; Scott D. Whittaker (SEM Lab Manager, Smithsonian Institution, Washington, DC) for assistance with the SEM work; Geoffrey Thompson (Visiting scientific illustrator, Queensland Museum, Brisbane, Australia) for the color habitus illustration of *T. wheeleri*; Taina Litwak (SEL) for digitally rendering the genitalic illustrations; A. G. Wheeler, Jr. and Lutz Rastaetter (Greenbelt, Maryland) for translating Josifov and Kerzhner's (1972) German description and discussion of *T. koreanus*; Sonja Scheffer and Matthew Lewis (SEL) for their discussions on barcoding specimens of *T. chinensis* and *T. parviceps*; and the Willi Hennig Society for sponsoring free access to TNT by Goloboff et al. (2008). This paper was initiated as a contribution to the NSF Planetary Biodiversity Inventory (PBI) award DEB-0316495 (2004–2008) to R. T. Schuh and Gerasimos Cassis, principal investigators (<http://research.amnh.org/pbi/>). R. R. Kula (SEL), M. G. Pogue (SEL), M. D. Schwartz (CNC), R. T. Schuh (AMNH), and A. G. Wheeler, Jr. (Clemson University, Clemson, SC) kindly reviewed the manuscript and offered numerous comments for its improvement. USDA is an equal opportunity provider and employer.
