Abstract

In this paper, two species of cotylean Platyhelminthes are recorded for the first time from Qeshm Island, Persian Gulf, Iran. Pictures are taken from living specimens to illustrate shape and colour, and stained sections and drawings are used to describe shape and organisation of some organs. Morphological characters of Persian Gulf specimens of *Tytthosoceros lizardensis* Newman and Cannon 1996 are compared to those of the type specimens of this species.

Platyhelminthes, new records, Qeshm Island, Persian Gulf, Iran

Introduction

Most polyclad flatworms inhabit coral reefs in tropical and subtropical waters, and are especially species-rich throughout the Indo-Pacific. They are found from the littoral to sublittoral zone, and are often associated with other invertebrates (Bolaños et al. 2007). The order Polycladida is divided into two groups, Acotylea, which lack a ventral sucker, and which is not recorded from the area until now. The second group Cotylea is characterised by possession of a ventral sucker. Among Cotylea, the family Pseudocerotidae contains many conspicuous and colorful species. The diversity of this group, however, is not well known,

The two pseudocerotids species *Tytthosoceros lizardensis* and *Thysanozoon* sp. have been reported from reef crests and slopes of Queensland and the Great Barrier Reef (Australia) (Newman and Cannon 1996), and were also mentioned in a multimedia CD on flatworm diversity (Newman and Cannon 2005) as being known from Indonesia, the Philippines, and South Africa. To date, there has been no record of these species from the Persian Gulf and the Gulf of Oman, or other parts of the northern Indian Ocean. In fact, little is known about the diversity and biology of free-living flatworms from this region, and only a few species have been briefly mentioned by Newman and Cannon (2005) from the Gulf of Oman.

To close this gap in our knowledge, we carried out a study on the intertidal polyclads of Qeshm Island located in the Straight of Hormoz between the Persian Gulf and the Gulf of Oman (Fig. 1). Among other flatworm species, members of the family Pseudocerotidae were very conspicuous and are here reported for the first time from the Persian Gulf.

**Material and methods**

Sampling was carried out during six field trips (November and December 2007, January, May, July and November 2008) from 14 locations along the intertidal zone of the, Persian Gulf, Iran (Fig. 1, Table 1). Flatworms were hand-collected and kept in separate sampling containers, and then brought back alive to the laboratory. However, most specimens autolysed during sampling or during fixation. The remaining specimens were photographed in vivo, fixed on frozen 10% buffered formalin, for at least 24 hours, and then transferred into 70% ethanol for preservation (Bolaños et al. 2007).

Whole-mounts were stained with acetic Carmine, dehydrated in a graded alcohol series and mounted on microscopic slides using Canada Balsam. Some specimens were embedded in Paraffin, and 5μm sagittal serial sections were obtained to study the reproductive system. Sections were stained with Mayer’s hematoxilin and eosin (Humphson 1972). Sections and whole mounts were studied under a compound microscope (ZEISS, Axioplan2, 459312), and a stereomicroscope (Wild, Herbrugg, 124074), respectively. Drawings and measurements were carried out with aid of a camera Lucida.

Specimens are deposited at the Zoological Museum of University of Tehran collection (ZUTC).

**Results**

Three hundreds ninety-nine specimens belonging to five different families of polyclads were collected, of which 80 specimens belonged to Pseudocerotidae. Those specimens were identified as belonging to the genera *Tytthosoceros* and *Thysanozoon*. 
First record of the family Pseudocerotidae the Persian Gulf, Iran

Tytthosoceros lizardensis Newman and Cannon 1996

Type location: Heron Island, southern Great Barrier Reef, Australia.
Type specimen: Queensland Museum, Brisbane, Australia WM QM (G210716).
Specimens examined: ZUTC Platy 1001, 1002.

Fifty-six specimens of this species were collected from two locations (Stations No. 1 and 2, Fig. 1, Table 1). Most specimens were found in groups of up to 20 individuals,

under rubble in intertidal pools, and on an orange sponge (*Clione vastifera*). Most specimens autolysed during sampling or fixation and only four specimens remained intact after fixation procedure. The following description is based on those four specimens.

**Description.** Sizes of specimens range from 22 × 38 to 30 × 46 mm; background color variable, mottled light brown or olive green with cream mottling composed of dots, forming loose transverse streaks medially and laterally, darker medially sometimes with a tinge of light brown medially and on the pseudotentacles; narrow marginal bands, black then grey interrupted with short white transverse streaks of microdots at rim; submargin narrow, either cream or transparent grey (Fig. 2); pseudotentacles ear-like, small, cream with mottling of light brown or olive between (Fig. 3); 70–80 cerebral eyes, arranged like a horseshoe, dorsal pseudotentacular eyes, scattered, with about 35 eyes (Figs 3 and 4); ventral surface of specimens cream with black rims, and very ruffled margins; anterior pharynx large and ruffled, 1/5 of the body length (8.6 mm), associated with 5–6 pairs of pharyngeal folds; mouth situated in the middle of the pharynx (Fig. 6C); intestine extending posteriorly, but not to the margin of the body; male and female gonopores posterior to pharynx, distinct sucker in mid-body proper (Fig. 5).

**Anatomy of Reproductive System** (Figs 6A, B, 7). Testes scattered throughout the body, vas deferens forming a network of thin tubes; single male copulatory apparatus with rounded-oblong seminal vesicle (456 × 336 μm), oval prostate oriented antero-dorsally (120 × 96 μm), deep male antrum (192 μm), penis papilla with short stylet (120 × 72 μm); female copulatory apparatus with wide female atrium (120 μm) and cement glands.

**Thysanozoon sp.**
Specimens examined: ZUTC Platy 1003, 1004, 1005, 1006, 1007.

Specimens were found individually, under rubble and rocks, in intertidal pools (Fig. 8). Twenty-four specimens were collected from Stations No.1, 2 and 5 (Fig. 1, Table 1).

**Description.** Body sizes range from 8 × 12 to 22 × 30 mm; body translucent, red-white mottled with white spot and dots (Figs 8, 9); dorsal papillae red (Figs. 10, 11); pseudotentacles ear-like and small; cerebral eyes form a horseshoe-shaped cluster; dorsal and ventral pseudotentacular eyes present in clusters; pharynx elongated about 1/5 body length (3.86 mm) with 6 pharyngeal folds; two male gonopores and a single female gonopore are present; sucker posterior to the female gonopore, placed about mid-body (Fig. 12).

**Anatomy of Reproductive System** (Figs 13, 14). Testes and ovaries scattered throughout the body, doubled male copulatory apparatus posterior to the male gonopores; male gonopores situated directly after pharyngeal folds; male antrum short and wide (477 × 378 μm), with pointed stylet (387 × 108 μm); seminal vesicle oblong and muscular (387 × 153 μm); prostate oval (180 × 90 μm) with a thin wall; large female gonopore posterior to male gonopores, female antrum short and wide (288 × 180 μm) with cement glands.
Discussion

In the present study, 56 specimens of *Tytthosoceros lizardensis* and 24 specimens of *Thysanozoon* sp. were found on the intertidal zones of the Qeshm Island, Persian Gulf. Identifications of the specimens are based on comparison of the specimens with im-

ages, the descriptions and keys of *Tytthosoceros lizardensis* and *Thysanozoon* sp. as provided by Newman and Cannon (1996, 2003).

Newman and Cannon (1994a, b, 1996a, b, 1997, 1998, 2000, 2002, and 2005) and Newman et al. (2003) supplied an overview over the family Pseudocerotidae in the Indo-Pacific region, particularly from Australia, Papua New Guinea and Micronesia, and reported numerous species. Here, the most specious genera are *Pseudoceros* and *Pseudobiceros*, but other genera like *Bulaceros* and *Tytthosoceros* have also been reported from the Great Barrier Reef, Australia, and Papua New Guinea.

To facilitate identification of species, Newman and Cannon (1994) erected six groups defined by their respective color pattern. Based on their specific color patterns, *Tytthosoceros lizardensis* and *Thysanozoon* sp. can be assigned to their group four, which contains species of cryptic coloration.

Because of their extremely fragile nature, only a few slides of sagittal sections were obtained, so the specimens of *Thysanozoon* could only be identified to genus level, but it might well turn out to represent a new species. Species of *Thysanozoon* are found circum-

globally in warm seas, but those from Qeshm Island closely resemble those mentioned in the multimedia CD by Newman and Cannon (2005) as originating from the Red Sea.

The specimens of *T. lizardensis* found in the present study were similar to those mentioned in the same multimedia as being reported from Indonesia. As summarized in Table 2, the comparison of the specimens with the original descriptions of *T. lizardensis* showed some differences. However, these differences are not important enough to further separate the Persian Gulf specimens at the species level.

Specimens of *T. lizardensis* were only found at two locations in a rubble-rocky and rocky habitat. All specimens collected were associated with and possibly feed on an orange sponge (*Clione vastifera*). Although careful samplings were carried out six times, specimens of *T. lizardensis* were only found during one excursion in December 2007. This study only covered the intertidal zones, and it is very likely that further studies in the subtidal zone may reveal more species of *T. lizardensis* and of other species of flatworms.
