## Abstract

Species in the class *Diplura* are recorded from Alaska for the first time. Two species, *Tricampa rileyi* Silvestri from Dall and Prince of Wales Islands in the Alexander Archipelago of Southeast Alaska and *Metriocampa allocerca* Conde & Geeraert from near Quartz Lake, southeast of Fairbanks, both in the family Campodeidae, are documented based on recently collected specimens deposited in the University of Alaska Museum Insect Collection. A brief review of the history of the documentation of the Alaskan soil microarthropod fauna is provided, as well as discussion of possible glacial refugia.

## Keywords

*Diplura*, Campodeidae, Alaska, new record, soil microarthropods, Protura, Symphyla, Pauropoda, refugium

## Introduction

Documentation of the Alaskan entomofauna has accelerated in the twenty-first century, with over 1.2 M specimens cataloged into the UAM Insect Collection since the year 2000 (<http://arctos.database.museum/saved/UAM-Insects-since-2000>). However, relatively little historic or current attention has been directed at the soil microarthropod fauna of Alaska, which likely contains many new records and species. This is expected, in part, because much of Alaska remained glacier-free during the Tertiary when most

of what is now Canada was buried under glaciers (Ives 1974, Matthews 1975, Behan 1978, Pielou 1991). Alaska acted as a refugium for taxa, many of which are potentially endemic (360 arthropod species), some of which were presumably eliminated or prevented from dispersing by glaciers elsewhere. These endemics are often wingless, blind, soil dwelling species such as the beetles *Chionotypplus alaskensis* (Smetana 1986), *Alaocybites egorovi* Grebennikov (2010) (known in Alaska from a fossil), and *Pinodytes borealis* (Peck & Cook, 2011), new taxa of which continue to be found (e.g. a flightless mecopteran *Caurinus tlagu* Sikes & Stockbridge, 2013). All fifteen species of Protura known from Alaska have yet to be documented occurring outside of Alaska, and are thus potential endemics (Nosek 1977, 1980, Allen 2007). The Pauropod (Myriapoda) fauna of Alaska comprises nine potentially endemic species (Scheller 1986). A single species, among the 11 known for Alaska, of soil centipede (Myriapoda: Geophilomorpha), *Escaryus paucipes* Chamberlin 1946, is a potential Alaskan endemic (Weber 1949). The UAM Insect collection has 10 specimens of Symphyla (Myriapoda) from the northern region of Alaska's Prince of Wales Island (<http://arctos.database.museum/saved/AK-Symphyla>), but these remain unidentified and there are no published records of Symphyla from Alaska that we are aware of. Although we have found no published records of Diplura from Alaska there are records of a Dipluran identified as *Tricampa* sp. from Prince of Wales Island recorded in unpublished documents (conference proceedings and US Forest Service reports) prepared by Carlson (1994, 1997, 2005). We have fewer records of potentially endemic Collembola – only two of over 200 species known for Alaska (*Spinonychiurus alaskensis* Pomorski & Kaprus, 2015 and *Arneria filiformis* Pomorski, 2000). We have started, but not yet finished, summarizing the mite fauna of Alaska based on the works of Behan (1978) and Marshall et al. (1987), in which potential Alaskan endemics are certain to exist. These advances in our understanding of the soil fauna of Alaska demonstrate the progress made since Hilton's (1931a, b) focused efforts to collect Diplura, Protura, Symphyla, and Pauropoda from Alaska, during which he failed to recover any of these taxa except Pauropoda.

This unique Beringian fauna has received relatively little entomological attention historically (Riegert 1999). No study has yet focused exclusively on these potential endemics. These low-vagility organisms, like those adapted to alpine zones, are of particular concern in a changing climate because dispersal to maintain their ideal conditions is difficult. We know the northernmost latitudes are warming and drying more rapidly than any other region on Earth (Serreze et al. 2000) and alarming ecological and physical changes are being seen in Alaska (Chapin et al. 2006). The boreal forest, which dominates much of this northern landscape, making up about 17% of the earth's land surface area (Bonan 1992), is the coldest forested biome on Earth and is filled with organisms adapted to low temperatures. Alaska has warmed about 2 °C since the 1950s and 3.5 °C in the interior during the winter (US Global Change Research Program, National Assessment 2001). The growing season has lengthened by about two weeks, shrubs are invading the tundra and alpine zones, fires are more frequent and intense, permafrost and glaciers are melting, and Alaska's climate is shifting beyond the physi-

ological optimum for one of its dominant boreal forest species, *Picea glauca*, white spruce (Veblen and Alaback 1996, Stone et al. 2002, Lawrence and Slater 2005, Sturm et al. 2005, McGuire et al. 2009, Beck et al. 2011, Juday et al. 2015). Additionally, the increase in extremes of warm temperatures in the boreal forest are associated with rapid maturation and increasingly large outbreaks of wood- and leaf-feeding insects, which increase stress to already moisture-stressed trees. Melting permafrost allows precipitation to drain, thereby drying the soil and further stressing the trees, making them more likely to burn. Post-fire successional trajectories have already begun to shift (Juday et al. 2015) – this region will gradually lose its conifers which will be replaced perhaps by something like an aspen parkland – a combination of patches of aspen within a shrub grassland (Hogg and Hurdle 1995). We sit on the edge of this enormous ecological transition unlike anything modern humans have experienced before. It is therefore with great urgency that we document the current entomofauna of Alaska. We herein report on the first records of two species of Diplurans never before documented from Alaska.

## Methods

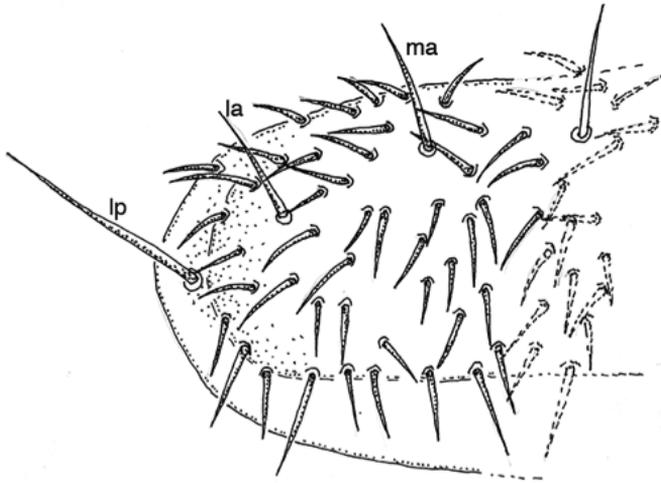

Specimens of *Tricampa rileyi* were collected primarily by forceps but also one specimen was recovered using Berlese funnels as part of two projects: Effects of forestry practices on ecological indicator species in the Tongass National Forest, Prince of Wales Island, Alaska and Baseline Community Surveys of Alpine and Subalpine Habitats in Southeast Alaska. As part of the Tongass sampling, BioQuip collapsible Berlese funnels were used with ~ 1 m<sup>2</sup> of leaf/moss litter sifted prior to running under 40 watt bulbs for 48h. The Berlese funnel sample came from a low elevation (41–45 m) old growth forest site. The rest of the specimens (n = 40) came from alpine and subalpine habitats between 540 and 881 m elevation. Details of habitat composition and links to photos of each habitat are available in the results below. Specimens of *Metriocampa allocerca* (n = 6) were collected by forceps in a mid-elevation (308 m) spruce forest as part of a general survey of the Quartz Lake entomofauna.

Preparation of specimens for study involved removing specimens from the ethyl alcohol in which they had been stored and mounting them on standard microscope slides. A small drop of mounting medium (polyvinyl alcohol) was placed on the slide, the specimen was then placed in the medium and positioned, and a cover slip added. The slides were allowed to dry for five days on a warm slide dryer. Specimens were then studied at 200× and 400× using a Leica DMKB compound microscope with phase contrast lighting.

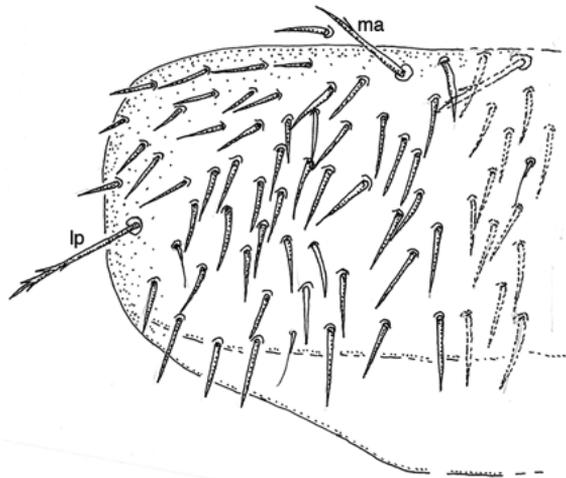

All specimens are deposited in the University of Alaska Museum Insect Collection and their data are available online at the links provided below. The data are also shared with iDigBio and GBIF.

## Results

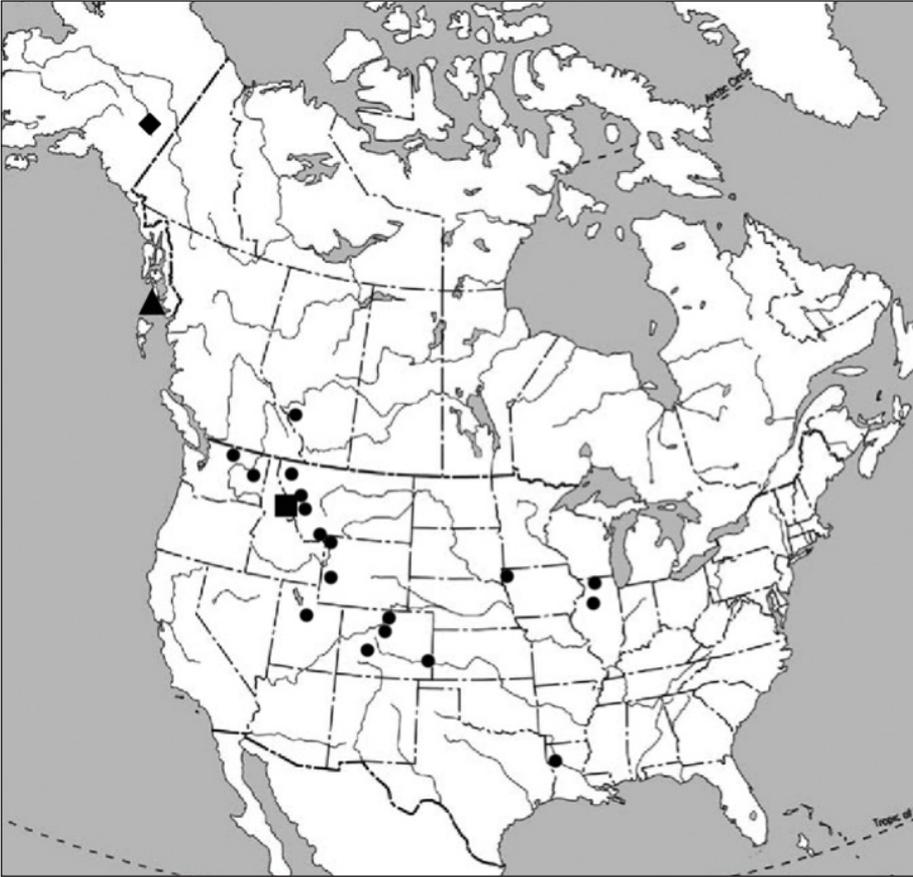

The two Alaskan species may easily be separated by the number of macrochaeta on the pronotum. Species in the genus *Tricampa* have three macrochaeta (median anterior, *ma*, lateral anterior, *la*, lateral posterior, *lp*) (Fig. 1) while species in the genus *Metriocampa* have only two pronotal macrochaetae (*ma*, *lp*) (Fig. 2). Figure 3 shows the known distribution of the two species. The following list gives most of the specimen data for these species in Alaska – complete data are available at the links provided (Table 1).

**Figure 1.** *Tricampa rileyi* Silvestri, pronotum.

**Figure 2.** *Metriocampa allocerca* Conde & Geeraert, pronotum.

**Figure 3.** Distribution of *T. rileyi* and *M. allocerca*: *T. rileyi*, circles = previous distribution, triangle = Alaska; *M. allocerca*, square = previous distribution, diamond = Alaska distribution.

## Discussion

*Tricampa rileyi* Silvestri, 1993 is the most widely distributed among the four North American species in this genus (Allen 1994, 2002). It ranges from Louisiana north to Illinois and Iowa, west into Colorado, Utah, Wyoming, Montana, Washington, and has been recorded from Alberta (Banff), Canada (Allen 2002; Schwaninger 1996). Collections reported herein extend this range into southern Alaska. *Metriocampa allocerca* Conde & Geeraert, 1962 has been recorded from only the type locality in Montana. The new record given here is from just southeast of Fairbanks, Alaska.

Species in both *Metriocampa* and *Tricampa* have been described from the Eastern Hemisphere. Three species of *Metriocampa* are known from Japan and China. One species belonging to the genus *Tricampa* has been recorded from Australia. Diplura found primarily in western North America have not been thoroughly studied nor has

the Asian dipluran fauna. It is highly likely that other North America/Asian biogeographic relationships will emerge as the faunae in the two regions become better known. Neither genus is known to occur in Europe but among the diverse European *Diplura* fauna none of the species have been recorded as far north (64°N) as the locality given for *Metriocampa* here (Paclt 1957). Lagerlöf and Andrén (1991) report on unidentified diplurans from central Sweden (60°N) and Reuter (1895) reported *Campodea staphylinus* Westwood from Kirkkonummi (Kyrkslätt) and Helsinki, Finland (60°N). These new northern records not only add additional distributional and biogeographic data to our knowledge of this group but also add to our knowledge about the environments and habitats *Diplura* are able to inhabit.

It could be argued that the rarity of diplurans in Alaska may result from a lack of effort spent using appropriate methods of capture. That is, if appropriate effort were expended, they would not be considered rare. We feel this is unlikely, due primarily to the state-wide collecting efforts of the first author, using the same methods which resulted in these two discoveries. Although as yet undocumented dipluran populations may occur in Alaska, given the effort to date, we expect there to be few.

Given that Prince of Wales Island was mostly buried under an ice sheet during the maximum of the late Wisconsin glaciation 26,000 to 13,000 <sup>14</sup>C years BP (Carrara et al. 2007) and had been repeatedly buried by ice during the Pleistocene, the presence of these low vagility organisms seems unusual. However, there exists considerable biological and geological evidence that suggests ice-free refugia in the Alexander Archipelago may have existed during this time, allowing organisms to survive in relative isolation, and re-seed the region after deglaciation (Carrara et al. 2007). Twenty seven of the 108 mammal species or subspecies occurring in southeastern Alaska are endemic to the area (Cook et al. 2001). *Tricampa rileyi* was recovered from regions that were reconstructed as under ice by Carrara et al. (2007, fig. 3). Post deglaciation dispersal to these sites from ice-free refugia is the most likely explanation.

The *M. allocerca* specimens were found at a site, Quartz Lake, that has received recent archeological study. Wooller et al. (2012) document the earliest human occupation of these sites at 13,100–12,700 cal yr BP and cite dates for the origin of the gravel terrace which formed the lake to between 140,000 and 40,000 years ago. The disjunct nature of this species with an interior Alaska population and a population in Montana is similar

to that of *Thanatophilus coloradensis* (Wickham, 1902) (Coleoptera: Silphidae) – a species known from interior Alaska and northern British Columbia in the north, and from elevations above tree line in Colorado, New Mexico, Utah, Montana and Wyoming in the south, with no intervening records (Anderson and Peck 1985). Genetic data would be needed to determine if this pattern is due to recent dispersal or ancient vicariance.

## Acknowledgements

We are grateful for our field and lab technicians Casey Bickford, Sayde Ridling, and Bennett Wong. We thank Kitty LaBounty who identified the plants of the alpine and subalpine sites. We thank David Klein who owns the property at Quartz Lake and encouraged DSS to collect there. Funding for this research came from two grants to DSS from the Alaska Department of Fish and Game.
